Both in the area of coal extraction as well as in that of crude oil extraction, the costs necessitated by the introduction of new techniques and of mechanization

and electrification of production have risen 2-3 times. It is natural for strictly necessary costs to be recovered through the production price so that the particular enterprises obtain the necessary profits to establish their own assets and provide material incentives for the workers. This also better stimulates the saving of social labor, the enterprises' concern for reducing production costs, primarily material costs.

Iosel Dicu: In accordance with the law, the industrial centrals are invested with a number of duties by virtue of which they have the opportunity to base their concerns in the area of cooperation and closing of contracts and the organization of production and labor in the enterprises. These major obligations can only be carried out by efficient participation in solving problems for the whole period of working out the plan and fulfillment of it.

Nicolae Gavrilescu: The demands imposed by the development and utilization of the energy potential of the county require raising the level of leadership of the party organs and organizations, having each organization and each communist carry out its and his role in uniting the workers' efforts to increase physical and net production and to obtain bigger and bigger profits. Striving to bring a qualitative leap in the work of the party organizations and to instill a dynamic style of work, we will be able to better implement the principle of worker and socialist democracy by having a more active commitment from the workers in fulfilling the tasks assumed. The results will be better if the collective leadership is efficiently united with each one's responsibility and work and the workers take action steadfastly as representatives of the owners and the producers. That is why we must improve the content of guiding the party organizations at the level of current requirements, eliminating routine, formal actions and humdrum work. We are tending to reach a situation where everything undertaken in each party organization should specifically answer a goal, mass political actions should be efficient, interesting and convincing while demanding ness should be demonstrated not in general but specifically toward the conservative, bureaucratic demonstrations. The new tasks referring to the move to a new quality require not only competence but also a new way of thinking, of taking action so that high economic efficiency is obtained in exchange for a greater creative effort.

STATUS OF YUGOSLAV FIRM IN WEST GERMANY

Hamburg DER SPIEGEL in German No 46, 10 Nov 80 pp 115, 117

[Article: "Something Is Going On"]

[Text] Koerting, the former People's Radio firm is currently managed by Yugoslavs--to date without success.

Two years ago, when the socialists from Yugoslavia assumed power over the bankrupt capitalist firm, they were unusually generous.

Oskar Pistor, new chief of the Koerting Radio Factory in Grassau on Chiemsee--which was bought by the Slovene Electro-Concern Gorenje, assured: "The enterprise will be administered by German managers in the future too."

The promise did not last very long. At the beginning of last month, the three German members of the Koerting management were relieved of their posts and replaced by Yugoslavs. Comrade Pistor can hardly be accused of breaking his promise: When his German colleagues on the executive committee were dismissed, he lost his beautiful job in the West as well.

In the meantime, the Yugoslavs also announced a "reduction in the work force." It has not yet been decided how many of the 1,400 Koerting workers, among them 300 Yugoslavs, are to be dismissed.

The German radio industry was from the very beginning suspicious of the peaceful coexistence between socialist and capitalist managers, because Bernhard Zumkeller, sales manager, Waldemar Moortgat-Pick, project manager, and Fritz Seyfferth, financial expert, were part of the management team when the old Koerting Works went bankrupt.

After the war, the firm--which during the time of the German Reich was very successful with the People's Radio--established too narrow an association with two partners. Koerting owner Gerhard Boehme sold his television sets primarily to the Neckermann mail order house and hi-fi equipment to the Elac Works in Kiel.

Both partners went downhill, one after the other. Neckermann was sold at a loss to the Karstadt department store concern, Elac went completely out of business.

The unavoidable demise of the old Koerting enterprise met with practically unconcealed glee among German competitors. After all, Koerting's Boehme had supplied the unpopular mail order house competition.

Nevertheless, the industry was quite unhappy,when, after a long search, Anton Jaumann, Bavaria's minister of economics, found someone who would rescue the bankrupt enterprise: Using an investment premium of DM 5 million, he attracted the Yugoslav Worker Concern Gorenje, an enterprise which, to be sure, was unknown in the West; nevertheless, it is not exactly a small enterprise. Today it has a sales volume of DM 1.3 billion and employs 18,000 people.

For a long time, specialty retail outlets which were catered to by representatives of the newly established "Gorenje Koerting Electronic GmbH & Co" would not let the representatives of the Grassau work forget the unsuitable liaison with Neckermann, the cheap retailer.

Soon it also became apparent that Pistor, the new Koerting boss, had bitten off more than he could chew. Instead of DM 216 million, as initially announced, last year's sales reached only DM 175 million. And there were no profits.

The gentlemen of the concern in Velenje, not far from the Austrian border, had given Pistor "a lot of freedom" (Zumkeller). It changed when at the beginning of this year a new man was elected to head the Gorenje concern: Gregor Svaiger, a trained engineer. Soon, more and more frequently Yugoslavs were looking after things in Grassau. Finally--3 months ago--Slavko Geratic, in charge of international marketing at Gorenje, settled in Grassau to oversee everything.

The Germans were right in suspecting that "something is going on." At the beginning of October, Svaiger suddenly replaced the entire management team. The Germans were demoted. Josef Pavlak from Velenje was promoted to the management position.

In Grassau, the times of beautiful freedom under socialist control are over. "The reins have been tightened," suspects a Koerting manager.

To be sure, this year the Germans can produce better results for their masters in the East: Last year's production of television sets (150,000 units) had already been reached by the end of September, sales are to increase by 2 percent and, at any rate, approximately 2,000 specialty retail dealers--one-fourth of the industry --are now carrying the Koerting brand.

But even this year it is unlikely that the coveted Western exchange will arrive in Velenje; there are still no profits. On the contrary: To be able to increase efficiency in production, the capital stock had to be increased by DM 20 million.

Gorenje has a difficult time on the Yugoslav market, which is plagued by crises. The managers from Velenje have every reason to watch the money of their German subsidiary. In the middle of October, Svaiger, the boss of the concern, paid a visit to the Minister of Economics Jaumann. In plain politburo style, the CSU man and the socialist announced subsequently that "a certain concentration and continued specialization will have to be achieved in Grassau."

Because in comparison to the Japanese competition, the personnel-intensive manner of production employed by the Yugoslavs and Bavarians seems still quite archaic.

Nevertheless, one factor remains to comfort the socialist owners. Christian-socialist Jaumann is underwriting up to 15 percent of the investments for modernization in a tourist region which has little industry--in spite of the fact that these funds will become the property of a socialist enterprise.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

CONFERENCE DISCUSSES IMPROVEMENTS OF GRAIN QUALITY, LIVESTOCK BREEDING

Sofia RABOTNICHESKO DELO in Bulgarian 27 Oct 80 pp 1, 4

[Round table discussion: "Topical Task of Science and Practice"]

[Protein--Basic Prerequisite for Resolving the Food Supply Problem

The 11th Party Congress and the National Party Conference, as we know, faced science and technical progress with important tasks and updated their development into a production force. The July 1978 BCP Central Committee Plenum extensively discussed the strategic directions of scientific and technical progress, indicating that the development of chemistry and, particularly, biology is the main way to resolve the number of vitally important problems, among which that of protein is considered the most important. This problem will be raised on an even more urgent basis in the biosynthesis of animal protein. Increasing livestock output presumes the food utilization of its biological advantages.

Based on the exceptionally important tasks stipulated in the party documents, the editors of RABOTNICHESKO DELO organized together with the Union of Scientific workers in Bulgaria a round table discussion attended by noted Bulgarian scientists and specialists. The discussion dealt with the role of scientific achievements in protein synthesis, i.e., the intellectualizing of the implementation of the most important task of the Eighth Five-Year Plan--intensification in livestock breeding.

The following participated in the discussion: Academician Kiril Bratanov, chairman of the Union of Scientific Workers and director of the Unified Center for Biology of the BAN [Bulgarian Academy of Sciences]; Academician Pavel Popov, chairman of the Grain Crops Commission of the NAPS [National Agroindustrial Union]; Professor Nikola Palagachev, head of the forecasting problem of the NAPK at the Scientific Research Institute of Economics and Organization of Agriculture; Senior Scientific Associate First Class Nikola Tomov, director of the Corn Institute in Knezha; Senior Scientific Associate First Class Trifon Dardzhonov of the Livestock Breeding Institute in Kostinbrod; Senior Associate First Class Todor Mitkov; Senior Scientific Associate Second Class Khristo Goranov, director of the Soybean Institute in Pavlikeni; and Scientific Associate Dencho Denchev, Institute of Microbiology of the BAN. This discussion was a subject we chose for our regular weekly topic on problems of public production intellectualization.

Selection Successes

Academician P. Popov: As was reemphasized at the National Conference on Grain Production, the grain problem is a strategic global problem of great political importance. I related it to the problem of proteins. This is based on the fact that with the development of grain production we are increasing protein production as well. I believe that our very useful discussion should focus precisely on this strategic step which we must take in the future: increasing grain production with a view to increasing the amount of protein. I bear in mind that at this stage we are obtaining our protein mainly from vegetal organisms. This possibility must be put to practical use.

Let us note that along with the development of new strains of intensive wheat, combining high grain productivity with high flour and bread quality, extensively developed over the past five years in our country, our selection work has scored steady progress in upgrading the protein content. This year we obtained, for the first time, an average of 405 kilograms per decare of wheat containing from 12 to 14 percent protein. Our objective, however, is to raise the protein content to 16-18 percent in soft wheat.

Lately there has been a particular increase throughout the world, including our country, in triticale--a new interstrain hybrid obtained by crossing wheat with rye--in connection with the development of new strains aimed at increasing grain production and raising the content of protein in order to meet animal husbandry requirements. Most scientists believe that the introduction of this new crop is one of the most significant accomplishments of world selection in the 20th century. That is why this year the Central Council of the NAPS drafted and approved a long-term program according to which by 1985 between 800,000 and 1,000,000 decares will be planted in triticale; 400,000-500,000 decares will be planted in low stem grain crops and as many will be planted in high stem grain crops for fresh feed (hay, silage, hay meal) and straw, yielding considerable economic results.

Professor N. Palagachev: I wish to emphasize that the problem of obtaining a unit of animal husbandry output with lesser outlays of fodder units and protein cannot be resolved merely by increasing grain production. More grain is needed. However, we must also have a great deal of high grade grass feed output from alfalfa, natural meadows, and all artificial and cultivated pastureland, as well as fresh and rough fodder. We can achieve our main objective by properly storing, processing and harvesting vegetal resources. The elementary truth, however, is that this is not being practiced. Anywhere you look you would see that the livestock is not eating alfalfa in the proper form but is consuming hay and straw or even straw-like products. Consequently, the problems related to the proper harvesting of fodder crops are very urgent. The reason for this weakness is that the qualitative and proper harvesting requires model equipment which is currently in short supply. Let us not even mention the fact that very few of the existing machines do not waste fodder.

We must equally make use of rough fodder through the rapid development of cattle and sheep breeding. Our country has considerable possibilities which, however, remain unused. For example, if you visit Mount Strandzha in the spring you

would see big areas of green grass which dries out in July and August and remains unharvested. Only a small percentage of it is used for the reason that, first of all, no beef cattle farms have been set up, sheep breeding has been poorly developed, and so on; secondly, when the vegetation is at its peak it is not mowed and used as hay, silage, and others. A second grass crop grows in the autumn, when the rains begin. This crop could be used as well. The activities of the APK [Agroindustrial Combines] must be focused in this direction.

The problem of the land arises in this connection. According to Western specialists, by the year 2000 the arable land will have been reduced by six to seven billion decares. A similar trend exists in our country as well. On a parallel basis, however, again by the year 2000, the overall agricultural output of our country should be tripled or quadrupled. Therefore, two conflicting trends develop. Naturally, agricultural output will be increased through intensification. However, the concept that it alone could compensate for a reduction in the size of the arable land is wrong. That is why the forecast on the development of our agriculture by the year 2000, formulated by scientific workers in the spirit of the party's decisions, shows a radically opposite direction in terms of the utilization of our land. The amount of land should be increased rather than decreased. The conclusion is that our country could double or triple its agricultural output. Grain production alone could be doubled on a per capita basis, reaching 1.850 kilograms. All such problems could be properly resolved through the application of all known achievements of scientific and technical progress, i.e., by intellectualizing agricultural work (use of high grade equipment, refrigeration, and modern warehousing facilities).

Underrated Source

Senior Scientific Associate First Class N. Tomov: Proteins are an irreplaceable component in human and animal food. That is why, along with insuring the necessary amount of food for each living being, we must seek means with which to compensate for the protein shortage. Considering the more restricted conditions prevailing in the case of traditional leguminous crops, corn assumes exceptional importance. An additional 25,000 tons of proteins could be obtained by increasing the protein content in the grain by only one percent, considering the 2.5 million tons of grain grown by the country.

The protein content in the grain can be increased through the development of hybrids with a 10-12 percent or higher protein content compared with the current 8-9 percent. Selection work, however, is considerably hindered by the polygenic nature of this indicator. It has been established that some 20 genes and gene systems are involved in protein synthesis in the grain. Their combination within a single gene (a combination of hereditary elements in the nucleus of the cell) is difficult.

Oypek 2 and Flauri 2 are two mutant genes which considerably increase the content of irreplaceable amino acids such as lysine, tryptophan, methionine, etc. Whereas standard corn contains 0.25-0.30 percent lysine in its dry substance, the carriers of the first of these genes contain nearly twice the amount of lysine--0.45 to 0.55 percent. This valuable biological discovery, made in 1963, changed the entire amino acid structure of the protein in a desired and sought after direction. Such corns are described as high-lysine content corns because of their increased content of lysine, which is the most important limiting amino acid. They are of interest to nonruminant animals and to people wherever it is used as a food source. Extensive studies have confirmed the great advantages and possibilities of high-lysine corn.

At the present stage our high-lysine hybrid corns such as Knezha 3, Knezha 32, and Trakiya, along with Soviet, Romanian and Yugoslav hybrids can meet current requirements because of their increased lysine content.

Important Protein Raw Material

Senior Scientific Associate Second Class Khristo Goranov: The great interest in soybeans is due, above all, to the high protein content in the soybean grain (averaging 40 percent) and its high effectiveness in animal husbandry, the production of protein-balanced human nutrition, and the creation of high grade industrial products for consumers and industry.

In order to improve scientific services in the production of soybeans in Bulgaria a specialized soybean institute was set up in Pavlikeni. Its purpose is to determine the strain structure, develop the necessary technology for soybean growing, and insure the microbiological production of the preparation Nitragin serving the needs of the entire system.

The effectiveness of the soybean produced is determined by the yield. Consequently, it varies in individual okrugs. On the national scale, however, soybeans remain an effective crop within the framework of the crop rotation system and its application in animal husbandry and the food industry.

Our country has the substantial potential for increasing the production of soybeans and upgrading its effectiveness. Above all, a fuller use must be made of the possibilities offered by the strains and the new technologies developed throughout the world.

Problems Awaiting a solution

Senior Scientific Associate First Class T. Mitkov: In the past 15 to 20 years we have replaced basic strains and hybrids four to six times. The various rayons are using the most productive and the most qualitative among them. However, the new requirements calling for the production of more grain over the next ten years raise new problems as well facing scientific selection workers and agrotechnicians, as well as the experimentation workers within the system of the State Strains Commission.

Above all, we need rich data on selection achievements in CEMA and on a global scale.

Another essential problem is that of improving scientific zoning and utilization of strains and hybrids. The currently followed principle is based on results obtained within a specific okrug. However, it is the result of the work of no more than one or two experimental stations. Yet, all of us know that zoning on the basis of data which do not cover the entire variety of natural conditions is incomplete. In a number of countries, including some members of CEMA, the strains are zoned on the basis of soil and weather areas, ignoring administrative boundaries. It would be expedient, for this purpose, to undertake the establishment of soil-weather zones in the production areas and to organize, wherever necessary, additional strain testing with experimental areas (something which is

being locally done[1]. We must also organize a single management of the entire experimental work with strains within a given settlement system. This will summarize and make prompt and objective use of the results obtained not only by experimental sectors but on an industrial basis as well along with other data.

Taking weather conditions into consideration, we must organize on a broader scale the development of early ripening strains and hybrids.

Based on the Criteria of the New Requirements

Senior Scientific Associate First Class Tr. Dardzhonov: From 65 to 85 percent of the energy and from 65 to 92 percent of the protein accumulated in the plants are lost in the conversion of the vegetal resources, which are the main source of animal husbandry raw materials, into milk, meat, and eggs. That is why upgrading the efficiency in animal husbandry is the main task of livestock breeding and of the Animal Husbandry Institute in Kostinbrod.

What are, in our view, the most important ways for the solution of the protein problem? The first is improving the approach used in the scientific assessment of the effectiveness of the rations used in animal nutrition. Emphasizing, above all, the amount of protein reached in the growth of the animals enables us to properly balance rations and improve their utilization.

Another direction is related to improving the quality of the sunflower and soybean groats which has an impact on growth. In this respect we should seek possibilities mainly in improving the production of groats by observing a strict technological regime. In the opposite case a valuable protein raw material such as soybeans yields only half of the expected results.

The use of grain crops richer in protein and, above all, the lysine-rich corn and barley, will be of exceptional importance in resolving the problem of the protein shortage which, in terms of our animal husbandry, consists mainly of a shortage of the amino acid lysine. The practical use of these strains would require, first of all, the solution of the price differentiation problem based on their protein and lysine content.

High effectiveness in the conversion of grains into meat and eggs could be achieved only by providing the necessary quantity of high quality protein. The full utilization of the solar energy and the chlorophyll of the vegetal cell, which are the basis of plant growing, remains, for the time being, the most accessible way for the solution of the protein problem in our animal husbandry.

The Microbiological Method

Scientific Associate D. Denchev: In our country the average protein requirement has been virtually secured. The trouble is that in this norm the share of animal protein reaches no more than about 50-55 percent of requirements. For this reason the need for animal feed rises sharply. This need could be considerably met through the use of microbiological and biochemical protein production methods.

Currently no more than a few units are engaged independently and almost isolatedly in work on problems of the industrial production of unicellular protein. Such lack of coordination hinders the focusing of all efforts in order to encompass

the problem simultaneously from several sides: the biological, technological, and nutritional. Furthermore, the reconstruction and modernization, which were planned 7-8 years ago, have not been carried out as yet and the technical condition of the currently existing plants for fodder yeasts does not allow the development of highly productive and inexpensive technology.

The wood oxidized hydrolysates are the basic raw material used in our country, found in adequate amounts. We could also use some agricultural (corn stalks, plant stems, fruit and vegetable waste) and industrial (alcohol residue, waste water, lignin from yeast production, milk curd, and so on) waste. We should also be interested in methods used to enrich straw and agricultural materials with microbial protein. The USSR, Czechoslovakia and the United States have already developed technological systems to achieve this. They could be adapted to our conditions.

Comment by Academician Kiril Bratanov

The achievements reached in the biosynthesis of protein are the result of the scientific interpretation of all stages in the course of this complex process and, particularly, comprehensive research conducted on an extensive international basis in the areas of manifestation of the intellectualization process in biology, genetics, biochemistry, and microbiology, i.e., of some forms of manifestation of the intellectualization process in biology. This method must be continued even more emphatically in the Eighth Five-Year Plan.

The statements made here prove that the protein problem could be considered in two aspects. The first is the study of protein as a basic component of animate matter. Today all basic and theoretical research in biology is focused on the study of the processes occurring in the protein on the molecular level. The task is not only their clarification but the scientific substantiation and development of technologies which would direct such processes in channels useful to man, i.e., the development of technologies for the industrial production of proteins at different levels. This includes the technologies for the intensification and upgrading the productivity of plants and animals, and the intensive production of biologically active agents and of protein and its components with the help of microorganisms.

The second aspect of the protein problem is to master already familiar technologies using industrial methods for protein biosynthesis and in order to increase its output. It is a question of increasing the amount of protein in its numerous forms. Both aspects of the protein problem are today an important task facing all scientific units in our country working in the field of biology.

One of the methods of increasing the amount of protein is the extensive use of industrial methods in animal husbandry. Recently they have been applied in our country not only in poultry and hog breeding but in cattle and sheep breeding as well. In order to increase the production of meat, i.e., of protein, the intensification of the breeding process makes a great contribution to contemporary sheep and cattle breeding. In recent years the Institute of Biology and Immunology of Breeding and Development of Organisms of the BAN has worked on technologies for the intensification of the breeding process in sheep, twin calving in cows and other methods for increasing animal husbandry output, i.e., the output of protein.

I believe that the entire protein production process in the area of animal husbandry must be paralleled, from beginning to end, by scientific and technical progress and, at the same time, supported by the latest scientific data. This will lead to the development of an integrated modern complex: science-research-experimentation-application-marketing. This means the intellectualization of the national economy.

INVOLVEMENT OF WORKERS IN MANAGEMENT CALLED FUNDAMENTAL

Bratislava PRACA in Slovak 24 Oct 80 pp 1,2

[Editorial: "Workers and Their Rights"]

[Text] Not only in our country but all over the world people have become conscious of Marx' thesis that the working masses shape history. Moreover, it has been found to be true that socialist society cannot arise and develop without restraints, and therefore the party must have a leading role in it, the state must fulfill the organizational, educational and administrative function, and the trade unions must play two roles in one. This premise applies simultaneously when expanded by the principle that the conception and development of socialism presupposes active and conscious participation of the workers not only in the socialist revolution, but also in the process of building a socialist society.

Why do we repeat these axioms? Because we are facing complex tasks, and because those tasks may be resolved only if public opinion supports us. Social opinions in places of work always represent the sum total of the workers' views and suggestions.

Of course, we are fond of saying--often enough--that our workers have the right to participate in the management and control of the production and administration of the economic sector, and the right to participate in planning of administrative measures, and that they have a voice in the decisionmaking process. We never forget to emphasize this fact in all our reports. Nevertheless, those principles when translated into practice frequently appear completely different. For instance, in a place of work a man complained quite recently that while taking part in a discussion at a trade union conference he was told by the executive board that "a trade union member has no business talking about the organization of the enterprise!" Naturally, this is not an isolated case demonstrating the lack of willingness to listen to the problems or suggestions of the people in the places of work. Many economists or officials as well look askance at the critic, however legitimate and objective he may be. By the same token, they never omit mentioning that every trade union member should be a manager of his place of work, without realizing that if we want to develop and strengthen the worker's managerial attitude--which determines the strength of the leading role of the workers' class--preconditions must be set for real participation in the decisionmaking process, the more so because workers, acting through their trade union, are directly responsible for decisions of numerous problems. Our workers must see and personally experience that management

f production involves the solution of all their problems related to their inter-
sts, demands and needs; their own experience must convince them that their word
as weight and that our society needs their cooperation in managing all its affairs.

xperience has shown that people in places of work call above all for improved qual-
tative indicators of democracy within the enterprise. They demand honest informa-
ion concerning current problems in the life of their enterprise, in order to be
ble to express their attitude even during the preparations for the decision, and
o make their views heard and considered during the decisionmaking process. Exper-
ence has shown that if the workers are excluded from participation in shaping the
ife of their enterprise and their place of work, then their interest in their
nvolvement in social affairs diminished, their creativity vanishes, and their ini-
iative declines. This is reflected in overall production as well as in their
nitiative at work, in socialist competition, in the atmosphere of their enterprise,
n interpersonal relations, and in relations between the management and the workers.
s it then possible to disregard the opinion of the workers?

evertheless, this also implies that every right of the trade unions must be inter-
reted in such a way that it does not belong to the trade union, but that it repre-
ents a legitimate right of the workers.

f course, we recognize in theory the role of trade unions in democracy within the
nterprise. We admit that the activity of trade union officials in plants and
ther places of work offers direct opportunities and organizational forms for the
orkers' participation in management, including the protection of their legitimate
nterests in relation to every level of economic management. In practice, however,
here has been too much pussyfooting and many things are simply swept under the
ug.

et us take, for example, consultations on production. Their entire history is
arked by an effort to overcome the controversies between their function as postu-
ated in theory and as it really is, and to give realistic contents to this method
f workers' participation. This effort has been demonstrated by the adoption of
he principles for the organization and procedures of consultations on production,
pproved by the CPCZ Cebtral Committee, by the CSSR Government and by the ÚRO [Cen-
ral Council of Trade Unions] in 1974. Those principles provided an institutional
ramework enabling consultations on production to fulfill their social purpose to
he fullest extent.

here is little doubt that over the years the number of consultations on produc-
ion and the number of the participants in them, as well as the ratio of implemented
roposals, have substantially increased, as have the numbers of places of work
here the views of the people are seriously considered. Nevertheless, in too many
onsultations not a single proposal is offered, nor are any decisions reached. May
his be the result of the predominantly informative orientation of such consulta-
ions on production? Naturally, the purpose of the consultations is to discuss
he tasks stemming from the fulfillment of the plan, and to define the tasks facing
hat particular place of work. Although it has been systematically stressed that
uch consultations should focus primarily on the qualitative aspects of management,
lanning thus far has resulted mainly in assessments of the volume of production.

Thus, the suggestions gathered in the consultations may often be summarized in a single demand: Provide us with adequate supplies of materials or parts and we will take care of the plan.

The improved planned management system, however, introduces indicators of adjusted value added and return on operating assets, and ties them also to material incentives. The same criteria must be applied also to the agenda of consultations on production, and the workers must learn that the resources for the development of every level of management, wages and cultural and social services fund will depend primarily on how much the whole collective can earn for that purpose; they must learn that it is more advantageous for them to accept more demanding tasks even in the plan. Naturally, in order to understand these and other correlations, and to inspire the workers for more economic management according to the principles of enterprise khozrashchot, proper preconditions must be created, which is primarily the task of the economic management as well as of the plant committees and of all trade union officials.

The Set of Measures stresses that consultations on production must be systematically focused on the solution of vital tasks of production. Thus, the decisive factor will be the extent to which the economic management and the plant committees will be able to introduce a better system into the life of workers' collectives and to include individual problems in the agenda of consultations on production. That, however, is not all. It is important to analyze the reasons why in some places the workers display very little activity in consultations on production, why the contents of the discussion demonstrate such great differences, and why they frequently tend to concentrate not only on problems of production, but also on other questions related to the workers' life, including social security in the enterprise. This indicates that the workers do not regard consultations on production as an institution which specializes in problems of production but rather as one serving multiple purposes. Moreover, this proves that in fact the work is not adequately divided between consultations on production and ROH [Revolutionary Trade Union Council] membership meetings.

All these problems must be recognized and resolved, if in every place of work in the next period we want to intensify our comprehensive efforts to develop activities and to intensify the initiative and coordination of work in sectors and workshops. This does not merely imply that the workers must be given general information and involved in such tasks, but also that their participation must be creative and bring specific contributions. This cannot be accomplished by mere appeals, challenges and proclamations of facts. The turning point toward overall peak efficiency in our national economy may be achieved by truly active participation of our workers in management and by their creative activity--and thus, also by the ability of the trade union movement to upgrade workers' participation in management. In all organizations and economic organs, however, this presupposes systematic respect for the rights of the trade union organs based on the decision of the Fourth All-Trade Union Congress. It is imperative to follow the Labor Code, to develop cooperation and joint activities, and to turn it into a positive factor in the development of dynamic powers of our economy.

Comrade Gustav Husak did not talk idly when he reminded the 18th Meeting of the CPCZ Central Committee of the fundamental, intrinsic task of the ROH, saying:

"Our policy will continue focusing on the development of the ROH mission in consolidating the workers' rights and interests and its coresponsibility for the solution of tasks relevant to our entire society, in resolving every problem of social development, and in improving efficiency and quality of our economic program."

ADVANTAGES, PROBLEMS IN BLOC TIES WITH 'MULTIS' ANALYZED

East Berlin IPW-BERICHTE in German Vol 9 No 10, Oct 80 pp 29-36

[Article by Juergen Nitz: "East-West Economic Relations and International Monopolies: Unity of Struggle and Cooperation Between Partners With Differing Social Systems--Economic Ties Strengthen Peaceful Coexistence." Translations of the following related information are available in JPRS issues of this series as indicated: same author, article cited in footnote 8 below, published under heading, "Socialist-Capitalist Economic Relations Problems Analyzed," in 69571, 9 Aug 77, No 1659, pp 1-124 and two earlier analyses (Oct-Nov 75) in 66610, 19 Jan 76, pp 12-49; East Berlin HORIZONT article by Max Schmidt cited in footnote 23, published in 74996, 24 Jan 80, No 1972, pp 28-41]

[Text] There is more and more talk in public, and in political and scientific organizations such as the UN, UNCTAD, ILO and UNIDO, about the role of the international monopolies in the world economy.[1] The focal point of many scientific publications in socialist and developing countries, but also of authors in capitalist industrial countries, is placed on the negative practices of the transnational monopolies in the economic, political and social fields and on recommendations to curb their activities.[2]

The critics of the multinational corporations proceed from the proposition that they today constitute the main form for the internationalization of the economy in the capitalist world economy. They also are the main pillar of the scientific-technical potential in contemporary capitalism. H. Beininger, for instance, reaches this conclusion: "On account of this economic potential and its ramified international structure, which includes the direct power positions in the economy of the states, they constitute a crucial factor in the international division of labor and the mechanism of international economic relations in the capitalist world economy."[3] It furthermore is being shown that they control the social structure in the capitalist industrial countries.

The compelling motive for their expansion within and to the outside has always been gaining monopolist profits through their overpowering position in the economy and their aggressive economic, political and military foreign expansion, especially vis-a-vis the developing countries, supported by the

monopoly-capitalist state. Increasingly the multinationals have started to use the state directly for their own expansive objectives. They occupy predominant positions in the raw materials economy, exploit the working people in their own countries and in other states in new dimensions, curb their national sovereignty and loot the developing countries. A special point must also be made of the danger to peace coming from the monopolies that deal with armaments.

The effect of the international corporations is not confined only to the capitalist economic system. Their activities also play a significant role in the important field of economic cooperation between socialist and capitalist countries.[4] It must be kept in mind that, on the one hand, the multinationals are a main partner of socialism in their economic relations between the systems while they still constitute, as the crucial social foundation of the imperialist system, the chief enemy of socialist progress in the world, which, among other things, results in a complex dialectical interaction between the cooperation and the class conflict of socially opposed partners. Cooperation and struggle in their contradictory unity cause positive as well as negative aspects which must be precisely balanced off with each other on behalf of socialism.

Remarkable Results

Thus far there have only been few instances of comprehensively and systematically investigating the considerable share the international corporations have in the trade with socialist states. Even so, such analyses yield the following:

We must proceed from the fact that many of the economically strongest corporations in the world have economic relations with socialist countries--even if they greatly differ in intensity.[5] Circa 1,000 of the 3,000 economically most important ones of them have economic relations with enterprises and institutions in five or more socialist countries. As the USSR occupies an outstanding economic position in CEMA, it is the country with which the most important contracts have been concluded.

Circa one-third of the multinationals having economic relations with socialist countries doubtless are among the "giants" in their countries. According to a survey of the mid-1970's which included 180 capitalist large-scale enterprises, 20 of them had capital assets of more than $ 5 billion, 24 of them, more than 3 billion, 73 of them, more than $ 1 billion, and 33 of them, less than $ 1 billion.

The largest share comes from the economically most important Western countries, with the international corporations of the United States, the FRG, Japan, Great Britain and France in the lead. A smaller share goes to monopolies of Sweden, Italy, Netherlands, Switzerland, Belgium and Austria. Now it must of course be kept in mind that in such countries as the FRG and France, and even more so in Sweden, Italy and Austria and in still smaller countries, far fewer corporations have their own corporate management than in the United States, but the share of these corporations handling East-West trade enjoys a higher place value in their countries' economic potential.

The international corporations are active mainly in the leading scientific-technical branches of East-West trade, for instance in plant construction, modern equipment, ADP installations, electrical engineering, the construction of scientific devices, and some areas of the chemical industry. Far less involved are the consumer goods industry (textile, glass and ceramics and food processing) and agriculture.

Some international monopolies have as a matter of fact a considerable share in East-West trade. There are some large-scale enterprises in capitalist countries that have geared a high percentage of their output to orders from the East. The Mannesmann corporation in the FRG, for example, has at times produced up to 70 percent of its tubing on orders from the USSR, whereby it became the chief supplier of seamless pipe for the CEMA area.[6] The annual export volume of DM 700 million from the Salzgitter corporation in the FRG to socialist states amounts to circa 25 percent of the corporation's total exports.[7]

Mainly for large-scale projects on a cooperation or compensation basis and in scientific-technical exchange, the partners and contractors found on the Western side are corporations. In 1976 alone, the USSR worked together with research facilities of developed capitalist firms on 600 scientific projects.

Many hundred multinationals have set up bureaus, outlets and so forth in capitals of socialist countries or in cities they regard as "turntables for East-West trade," for instance in Vienna.

The big capitalist banks play an increasing role in East-West economic relations, mainly those of the United States (with circa 20 percent of all the banks working in this field), Japan (20 percent), the FRG (15), Great Britain, France and Italy (circa 10 percent each). Credits are principally used for supplying equipment.

The GDR--along with the other CEMA member countries--also of course maintains intensive relations with many leading industrial enterprises and banks in capitalist industrial countries, as shown especially by business contracts with firms in France, Italy, Japan, the FRG, Sweden, Austria and so forth. At the Leipzig fairs alone, circa 2,000 international corporations are represented directly or indirectly. Circa 100 large FRG corporations with an export volume of 2.5 billion valuta mark were part of GDR imports in 1978.

What explains these no doubt important relations between the enterprises, combines and foreign trade organizations of the socialist countries and the large Western corporations? What turns the latter into a useful and interesting economic partner of the CEMA countries?

Important Economic Factors

From the special vantage point of the socialist countries, the economic factors should first be mentioned. Let us start with the observation that the general interests of the capitalist states and corporations in trade with

socialist countries do not differ in essence from the specific interests of the big international corporations. Here then too, first and foremost, such general capitalist interests are most pronounced as the use made of capital, the expansion of sales, higher capacity use, the diversification of raw material and energy supplies, the securing of jobs and so forth. What is at stake here is obtaining economic advantages and profits from the objective process of the growing internationalization of economic life under the conditions and requirements of the scientific-technical revolution.[8] With it, however, the international corporations are introducing some particular factors into mutual economic relations which principally evolve from their organizational and productive strength and mobility.[9]

The big corporations with their important production and R&D possibilities are the main source of the latest technologies in the Western countries, which the socialist states are interested in purchasing. The magnitude of their potential enables the multinationals to hold the lead in many economic and technical fields. Abandoning economic relations with them would reduce the socialist countries' gains in growth and effectiveness--while at the same time hurt the interests of the capitalist side as well.

Due to their multifaceted production assortments and their skill in commercial operations at large dimensions, they are virtually predestined for large-scale orders and investments in the various branches of industry. And it is precisely such projects that the socialist countries are planning, as for instance the extraction of petroleum and natural gas deposits in the USSR, the construction of large-scale chemical plants in the GDR (Schwedt, Buna II) and so forth.

The corporations are especially suited to compensation arrangements as they are in the position to direct and distribute compensatory deliveries through enterprises they own or through their business partners. An example is the plant that makes drive shafts that is being built with the French Citroen Corporation near Zwickau. Another one is the reconstruction of steel plants in the GDR.

For the development of licensed production, that is for the contractually arranged manufacture of products of leading capitalist corporations in socialist enterprises, mainly in the form of compensatory transactions, high-quality products and brand commodities are wanted which the multinationals primarily have been introducing at Western markets. The GDR has concluded such contracts, for instance, with leading corporations in the FRG, Austria, Switzerland and so forth in the consumer goods industry.

The big capitalist corporations are in the best position to insure the sale of jointly manufactured products coming out of a division-of-labor corporation in the nonsocialist economic region since they have multifaceted distribution networks available there. VOEST-ALPINE in Austria, for instance, has just set up its own sales organization in Linz which also organizes sales to third countries.

Orders often are handled by subsidiaries and branches the production activities of which are directly or indirectly subordinated to the interests of the corporation. More than 30 Italian firms belonging to ENI and Montedison are carrying out joint investment programs in chemical complexes of the USSR.

The monopolies are potent buyers of large quantities of products from socialist countries. Raw material and fuel shipments are gaining increasing importance in this. Especially department-house corporations are buying considerable volumes of industrial consumer goods, manufactured in series production in socialist countries. But the big corporations also increasingly appear as purchasers of equipment from socialist countries. "Many readers will be astonished to learn that the multinational corporations now also belong among the importers of manufactured commodities, tools, machines, transport commodities, even whole industrial installations, from the socialist countries. It is in fact ironical that some of the products the socialist states export to the West once were placed on the West's strategic embargo list vis-a-vis the East," as J. Wilczynski has observed.[10]

The big Western industrial monopolies are as a rule affiliated with financially potent banks which can make available copious credits requisite for large-scale projects and compensations business. For some large contracts, credit operations have meanwhile reached amounts of several million and even several billion dollars, magnitudes that can no longer be coped with by individual banks but only by consortia.

Finally, because of their structure, international corporations are suitable for economic relations with the combines and foreign trade organizations in the socialist countries. The latter, as the Czech economist J. Vrany points out while quoting the bourgeois scientists J. Wilczynski, have set up a most effective system of legislative, institutional and procedural measures for negotiations with the international capitalist monopolies. They, however, are not permitted to become predominant in the economy of the socialist states or indispensable for investments or for economic development."[11] And Professor F. Knirsch of West Berlin has made the point that the large-scale enterprises of the West have more experience in dealing with socialist states than the smaller firms. For the socialist foreign trade organizations it would also be less complicated to do business with a small number of large capitalist firms and make it more of a long-term business (of benefit to socialist planning) than with a large number of small Western companies.[12]

Ultimately, the cooperation with capitalist states also involved the solution of such global problems that have to do with environmental protection, transport and energy and fuel supply, for which once again the large capitalist corporations are the potent partners.

Economic Relations With the Multinationals Cause Many Problems

The socialist countries' relations with the international monopolies are of course not unproblematic, given the mere fact that the latter seek to reach economic objectives resulting from their class interests, which in turn are in principle opposed to the socialist states.

This attitude of the capitalist large corporations also is often being discussed in public. The U.S. economist William Diebold Jr. said at a symposium that "the multinational corporations still engage in their 'normal activities' in their industrial cooperation with the socialist countries, which means they cannot and will not change their business attitudes. Whether they do business in East or West, their cooperation will be marked by their profiteering."[13] So one can be surprised that the monopolies seek profits when trading with the socialist countries. That, after all, is germane to the capitalist system.[14]

This basic interest makes contracts with corporations both possible and difficult because, with it, the principle of mutual advantage must be observed. Among the disturbing factors are, no doubt, attempts by the monopolies to turn over to the socialist countries products that are harmful to the environment even though, in general, the capitalist side is pledged to international cooperation in the field of environmental protection. Moreover it seeks to use economic areas in the socialist countries as an "elongated workbench" for the international monopolies, i.e., seeks to have the CEMA states handle relatively "simple" productions while reserving "intelligence-intensive" productions for the monopolies.

In many cases the corporations offer products to the socialist countries that do not meet with highest standards so as to obstruct technical progress in socialism. And they also seek to interfere on the markets and so forth. P. Knirsch points out that the multinationals "embody a commensurately large market power and can in some cases apply monopolist modes of conduct in international economic relations too. This market power they will necessarily seek to use against any trade partners, which also includes the socialist countries." He adds, however, that the "concentration of the foreign trade authorizations in the socialist countries," that is the socialist state monopoly in foreign trade, certainly remains able "to curb the market position of Western large-scale enterprises."[15]

It would make no sense to reject the economic relations with the international corporations simply because they pursue the designs alluded to. The Romanian scientist I. Serbanescu, for instance, has said: "We must accept and even encourage these relations but see to it that the forms used will turn these relations into genuine cooperation. Forms must be found, in other words, that would prevent those corporations from gaining control of certain areas of the economies or from using practices that would have detrimental effects on the interests of other countries."[16]

Thus we must always, in general and in any individual instance, act in accordance with the consideration for what is useful for socialism or how imperialist attempts at hurting socialism are to be prevented. In their cooperation with Western corporations, the socialist countries of course pursue economic interests that are specific to their system and are aimed at using advantages from the international division of labor for their own development. Cooperation with the monopolies serves as an important supplementary source of activities within the framework of the socialist plan economy, including the economic integration within the CEMA framework.

This way economic tasks can be solved that could otherwise not yet be tackled at this point or completed with the same rapidity or on the same high level.

This then is not merely a matter of an "altered distribution of benefits in the East-West business," as W. Meissner of Frankfurt/Main University presumes,[17] but of constantly enforcing the principle of mutual advantage, the essential element on which the foreign economy relations of the socialist states are based. The points of intersection in interests as well as the divergencies within the economic relations between socialism and capitalism have to be embedded within the policy of peaceful coexistence between states with differing social systems, for which--also in the view of more realistic imperialist circles--there is no other acceptable alternative for mankind. As the material foundation for the process of political detente, the socialist countries are thus developing economic relations with all essential elements in the capitalist industrial states, with the larger as well as the smaller enterprises.

The 'Large' and 'Small' Ones in East-West Trade

The West not infrequently accusesthe socialist countries or foreign trade organizations they are "not doing enough" for the "small ones," that is, enterprises in the small and medium-size industry, in East-West trade, and are placing them at a disadvantage for the benefit of the "large ones," the monopolies, in particular the international corporations.[18] What actually is one to make of the role of the "small ones" in East-West economic relations?

No doubt there are these contrasts and contradictions between the "large ones" and the "small ones." The first point to be made here, however, is that they are caused by the capitalist production relations and the contradictory developments in capitalism itself. Under the pressure from the multinationals, more and more small and medium-size enterprises are getting into economic difficulties and are ruined. So this amounts to an objective problem in the capitalist world economy. The contradiction is not the outcome of the antagonism between socialism and capitalism, and it has in no way been caused by the former. And so one cannot blame the socialist states for the differences existing in the possibilities for participating in foreign trade as between capitalist large and small-scale companies.

Nonetheless it can be seen that the opposition inherent in capitalism between corporations on the one side, and the middle-class and petty bourgeoisie, on the other, also in a certain way is reflected in East-West trade. The CEMA states, to be sure, offer no unilateral advantage to the "large ones." The socialist countries maintain well-balanced relations both with the corporations and the small and medium-size companies. A Soviet study relevant to this, presented at the 12th International Eastern Trade Seminar in Bad Ischl by the representative of the Soviet Chamber of Industry and Commerce, G. Doneman, indicates the following:

More than 1,500 FRG corporations hold trade contracts with Soviet foreign trade enterprises in 1977. Almost 1,400 of them were small and medium-size enterprises accounting for circa half of the FRG trade with the USSR. Medium firms furthermore have the possibility to participate as ancillary suppliers for large-scale projects in the Soviet Union. Doneman presented some examples in this context. It turns out that in the construction of the world's largest truck factory on the Kama River, at the Chkalov natural gas complex, and at the Ust-Ilimsk lumber processing complex, 500 small and medium-size enterprises are participating along with some large-scale French corporations. In equipping two methanol plants in the USSR, 200 British small and medium-size companies are involved among others.[19]

The importance of GDR commodity transactions with enterprises in this order of magnitude is underscored by a study of the Institute for Middle-Class Research, Research Group Bonn of 1978.[20] According to that study, more than 70 percent of the FRG companies engaged in GDR trade are small and medium-size enterprises, i.e., enterprises with a labor force below 500. A detailed look shows that 366 of them--i.e., nearly 20 percent--even had fewer than 50 employees in 1977, which makes them small-size enterprises. Some 31.5 percent employed between 50 and 199, and 20.5 percent between 200 and 499. "The size structure of the FRG firms supplying the GDR with goods indicates that small and medium-size enterprises not only take part in this trade indirectly as ancillary suppliers but actively in the trade relations," as the study referred to summarizes the situation.

As to the branches the enterprises analyzed belong to, the emphasis clearly goes to machine construction (37 percent of the enterprises). "This means that an industrial group with a markedly middle-class structure significantly contributes to deliveries to the GDR. Other important industrial groups are electrical engineering and the chemical industry, which both are branches where larger enterprises rather predominate. Yet even in these fields, a relatively large number of small and medium enterprises participates in deliveries to the GDR."[21]

The survey by the Bonn research group is corroborated by various other analyses produced both in the FRG and the GDR, which reveal the following: At present there are circa 5,000 trade partners of the GDR in the FRG and in West Berlin, roughly 100 of them important, mostly international, corporations, 800 large-size companies and circa 4,000 small and medium-size enterprises, which annually conclude approximately 10,000 contracts of various kinds with GDR enterprises. Between 1978 and 30 June 1980, according to the FRG Ministry for Economics, the GDR imported from the FRG machines, installations and equipment and electrical devices at a total value of more than 3 billion valuta mark. More than 1,000 noted middle-class enterprises are participating in it.

Not only is the share of small and medium-size enterprises very high in the total number of companies, their share in the trade turnover between the GDR and the FRG or West Berlin is very high as well. Circa 50 percent of this overall trade turnover is handled by small and medium-size companies. And the role of the "small ones" is significant in both export and import.

The imports in 1978 involved along with 100 corporations with shipments at a level of 2.5 billion valuta mark all other enterprises with approximately 4 billion. Especially engaged are enterprises in branches that have efficient lines of special machinery to offer. Furthermore smaller enterprises appear as subsidiary suppliers in the implementation of large projects contracted for between the GDR and the FRG, partly on a compensation basis. In the construction of the Buna - Schkopau complex alone that involved 200 FRG firms.

Thus the GDR takes into account that especially enterprises in the so-called middle-class industry carry much weight in the development and supplying of modern equipment and that scientific-technical progress plays a great role among them too. They are very flexible in their fields and are forced to react rapidly by the competition from the monopolies. Often their production assortments supplement what the corporations have to offer.[22]

When the GDR supplies the Western states, the "small ones" also are fully integrated as buyers. GDR exports to the FRG in 1978, for instance, amounted to circa 700 million valuta mark to the larger corporations and roughly 3.5 billion to the small and middle-size enterprises. The GDR seeks to promote the "small ones" in East-West trade by still other ways and means, however.

At the Leipzig fairs at present circa 75 percent of those who exhibit belongs to the group of firms called "middle-class industry." All this reflects a GDR economic policy with a long-term orientation which grants the small and medium-size enterprises of Western countries a solid position in GDR import and export.

However much the socialist countries are doing to promote their economic relations with the "small ones," there is one thing that still has to be underscored with emphasis: They too are enterprises of the capitalist system, and their "survival" possibilities are not a problem of socialist trade policy but one of its inherent inevitabilities. That also is the position from which alone the question can be answered of who in East-West trade has the obligation to do something for them. The responsibility of the West doubtless is unequivocal.

On the part of the capitalist governments and other official institutions and organizations and so forth, there are various promotion measures for small and medium-size enterprises, such as, for instance, economic consultation offices in the FRG embassies in Moscow, Budapest, Bucharest and now also in Prague. Some Western countries have taken initial steps in organizing the small and medium-size enterprises for East-West trade under a "government umbrella." Commercial consulting firms with government help or government-sponsored have been set up that exercise consulting and organizational functions, such as, for instance, "Berlin Consult" in West Berlin which also maintains active business relations with the GDR.

And then there are the well-known attempts at setting up "promotion bureaus" for the "little ones" in Western countries. That includes there also the activities in developing or founding cooperation centers in which enterprises can coordinate their interests or get advice and counsel for East-West trade

and so forth. Criticism expressed by the small and medium-size enterprises of the work of many of these institutions confirms once again that lack of promotion can by no means be blamed on the socialist states.

State Monopoly Mechanisms Do More for the Multinationals

Specialized circles in Western countries note that the measures engaged in by the capitalist state in its trade with socialist countries are adapted to the needs and interests of the large corporations. Through economic associations and entrepreneurs organizations, where the representatives of the leading corporations have the say-so, through their direct brokers in parliament and its commissions and within the government, with the help of the in part strongly developed industrial lobby, the corporations affect the legislation and various economic policy measures and regulations in the capitalist countries. They get credits at favorable interest rates or with government subsidies attached or they are stimulated toward "Eastern trade activities" by government securities, as in the FRG. This applies particularly to large-size orders.

The agents of leading corporations have the say-so in the state monopolist institutions of East-West trade (in the FRG, for instance, in the "Eastern Commission of the German Economy"). They also appear as the repreentatives of the West in mixed international commissions, as experts in specialized commission and so forth, where economic cooperation with the socialist countries is under discussion. Measures practiced by the capitalist industrial states that obstruct East-West trade, such as customs or the fixing of quotas and so forth, in many cases are due to the interests of the monopolies. To the extent that such or similar measures affect the interests of the monopolies, they are a subject of constant domestic policy debate.

Concerning Some Political Factors

The economic relations of socialist states with international corporations amount not merely to relations between partners in economic enterprises, organizations, institutions and so forth as such. In consequence of the socioeconomically opposed property and power structures in the two social systems, they are by no means politically neutral in value as some ideologues in Western countries claim they are. These are reciprocal relations of socially differing classes on an international level and essentially a part of the conflict between the two systems. The socialist states take that into consideration, of course.[23]

For one thing, the socialist countries understand that precisely the transnational corporations have considerable influence on the governments in the countries in which they carry out their activities or have their corporate management. What could possibly make more sense than engaging with them in the kind of relations that would induce them to influence any of these governments in terms of consolidating peace and developing peaceful coexistence and to move them positively toward more realistic positions in their foreign policy vis-a-vis socialist countries, if for no other reason than that a departure from the process of political detente could have direct economic disadvantages for the large-scale corporations concerned?

Under that aspect the economic cooperation with the international monopolies transcends socialism's desire to strengthen its own foundations. It serves to enforce peaceful coexistence, to consolidate world peace and hence the interests of all peace-loving people. This neither does away with or weaken the contradiction between the workers class in the capitalist industrial countries fighting for social progress, peace and democracy and the monopoly bourgeoisie historically condemned to perish. Rather, through the policy of the socialist community of states better conditions are created for the social struggle of the workers class and all working people than had been possible under the conditions of the cold war or the dangerous confrontation between socialism and imperialism.

Developed economic relations with socialist countries or sound prospects for them can induce an attitude in the international corporations that is conducive to detente and disarmament. But on the other hand it would be illusory to assume that this is an effect they would necessarily have, inasmuch as the military-industrial complex most unequivocally exercises a crucial influence within the main NATO powers at this time.

And then again it should not be ignored that the large corporations tend to develop or stimulate political activities against socialist countries that are in essence anticommunist even if they appear neutral in terms of class interests. So it makes no sense to talk about a "harmony of interests between the multinationals and socialist enterprises or countries," as alleged, for instance, by leading representatives of Western organizations.[24]

Each side proceeds from its own class-bound social interests and thus approaches this cooperation in different terms. The economic relations of the socialist countries or enterprises with transnational corporations thus amount to a dialectical unity between struggle and cooperation by socially opposed partners, to a unity of contradictions. Yet they are being dealt with not by military means but by means that conform to the conditions of peaceful coexistence.

Clear Differentiation Processes

As there is no uniformity of attitude in the Western governments, there neither is any in the position of the international monopolies in the various capitalist countries on economic cooperation with the socialist states and their enterprises. That is seen particularly in recent times by the influence of a tougher U.S. imperialist policy against the Soviet Union.[25]

For instance, current attempts by the United States to drag other imperialist countries into its course of confrontation directed against detente and peaceful East-West cooperation are being rejected by many Western governments as well as by representatives of the international monopolies, especially in Western Europe. That is true particularly of France and such nonalined countries as Austria, Finland and Sweden but similarly also--as far as the defense of economic positions is concerned--of the FRG. There we find almost

unanimous pronouncements on this matter by Federal Chancellor H. Schmidt, Minister for Economics O. Graf Lambsdorff and the leading circles of FRG monopoly capital (for instance by DIHT President Otto Wolf von Amerongen),[26] advocating the further development of economic relations with socialist countries, which also is reflected in their economic policy and practice.

This evidently is greatly affected by the different interest situations of the various capitalist monopolies and their countries in East-West trade. Looked at it from this vantage point one must remember that the FRG alone had a 27-percent share in East-West trade in 1979, France one of approximately 10 percent, all EC states together circa 60 percent, all of Western Europe as much as circa 75 percent, yet the United States less than 10 percent. There also are many international monopolies in the United States itself that do not support the aggressive Carter policy. They include, according to their public pronouncements, Occidental Petrol, Armco Steel, Dresser Industries, Honeywell Inc., Pan American World Airways and others.

As the military-industrial complex is closely intertwined with the state monopoly government system and its political representatives, the result is that those U.S. corporations exercise the main influence right now which are interested in exacerbating East-West relations. They determine the U.S. government's course of confrontation. A similar trend is also found in the position of the British government and in the political positions of the CDU/CSU in the FRG, which in many respects oppose the basic requirements of an East-West trade based on mutual advantage.

For a Democratization of Economic Relations

The socialist countries proceed from the consideration that the negative effects on the world economy resulting from the activities of the transnational corporations must be curtailed or prevented. Their policy underscores the intention to bring about relations on equal terms among the participants and turn back or eliminate the especially harmful international practices of the imperialist side. Economic relations with monpolies internationally active are feasible only if they recognize a number of essential prerequisites that are part and parcel of peaceful coexistence, as for instance: the recognition of or respect for the political system or the social conditions of the other side; nonintervention in its internal affairs; respect for territorial integrity and sovereignty; and renouncing subversive activities directed against the partner and so forth.

All these maxims are by no means accepted from the outset by the monopolies and taken account of in what they do. In fact they contradict their character and goals. Making democratic principles prevail in accordance with the principles of peaceful cooperation therefore is an area of tenacious struggle through which the negative activities and at times also the hostile intentions of the multinational corporations are turned back.

The concrete East-West economic contracts demonstrate that in this field of world economic relations it is impossible for the transnational corporations

to put their hands on the raw material resources of the other side and exploit its manpower potential. That also holds true for setting up mixed corporations in the territory of socialist countries subject to their laws. Prices cannot be dictated but they become subject to well-balanced accords between equals. The socialist ownership in the means of production, the political rule of the workers class, the socialist planned economy and the socialist foreign trade state monopoly insure that the East-West economic relations, including those in which internationa. monopolies participate, serve the development and consolidation of socialism.

Establishing contracutual rules with the transnational corporations often is a complicated process because the monopolies maintain their characteristic features when dealing with their socialist contract partners and seek to make them prevail through stubborn negotiations. Any accord with them can therefore be understood only as the outcome of struggle between opposing interests.

The general efforts and advances toward the democratization of world economic relations also have positive effects in this context because the practice of economic cooperation for mutual advantage among the socialist countries is an effective example for it.

The further development of East-West economic relations, including the participation in them by the international monopolies, will no doubt contribute to the formation of a new international economic order, which in turn will be conducive to the economic relations between socialist and capitalist countries.

FUTURE OF EAST-WEST TRADE VIEWED

Budapest MAGYAR HIRLAP in Hungarian 23 Oct 80 p 5

[Report by Dr Andras Kovacs: "The Future of East-West Trade"]

[Text] East-West trade increased faster in 1979 than any time since the mid-1970s: the value of the CEMA-country exports exceeded the previous year's level by 35 percent, and their imports by 29 percent. Most of this increase, however, was the result of price increases and not the increase in volume, but the latter was also noteworthy. This is especially true of the CEMA-countries' exports, the volume of which exceeded the previous years' average significantly—by an estimated 10 percent. The estimated 6 or 7 percent increase in the volume of imports is very slight when compared to the usual pace of the 1970s: there was only a single year—that of 1977—when the CEMA-countries were able to decrease their imports from the West by a greater degree, i.e., by almost 7 percent.

The Situation Today

As a result of the differences in the increase of exports and imports, the CEMA-country trade liabilities decreased substantially in 1979: it hardly exceeded 2 billion dollars. This sum is only one-fourth of the record deficit of 1975 (6.2 billion dollars), and is much lower than that of 1978. Since the CEMA countries consider the improvement of trade balance their most important short-range economic goal, this is looked upon everywhere as a positive--if not always a satisfactory--development.

Behind the compound data above, there is the different balance situation of the Soviet Union and the smaller CEMA-countries. According to the OECD statistics the Soviet Union for the first time since 1974, achieved a balance surplus in its trade with the developed capitalist countries. This was made possible, in addition to a 22-percent increase in imports (which is higher than the CEMA countries' increase), primarily by a new increase of its export prices.

The tendency of deficit decrease is also shown by the data of the six smaller European CEMA countries. But the pace of the decrease is much slower. The six countries' combined deficit was about 3 billion dollars in 1979 alone; this is compared with the 4.5 billion-dollar deficit of 1975 and the 4.1 billion-dollar deficit of 1978. Still, the annual 25 percent decrease of the present foreign trade deficit is, by all means, a respectable achievement in the midst of unfavorable price developments.

The question is, however, what consequences can be drawn for the future from the present balance situation. Even the repetition of the 1979 export increase is difficult in the present world economic situation. The cyclical situation is worse when compared to that of 1979. According to an analysis made at the Business Cycle and Market Research Institute, we cannot count this year with an economic growth in the developed capitalist countries that is faster than 1 or 1.5 percent--as opposed to last year's 3 percent growth--and the increase in world trade will hardly exceed 3 percent. Higher figures for next year cannot be predicted with certainty either--even if the global situation is likely to improve slightly instead of becoming worse.

In principle, the slow increase in world trade does not exclude the possibility for certain countries or groups of countries to increase their exports to less dynamic or stagnating markets by pushing others out of the market. This is the traditional strategy of countries which are increasing their exports dynamically. It is to be feared, however, that the increase of the European CEMA countries' exports, with their level of economic efficiency and development, their pace of changing the product structure and their well-known problems in export production and trade, cannot permanently and significantly exceed the rate of increase in world trade. This question leads us to the fundamental problems in economic policy which are related to the trade between East and West.

The Gaps of Improving Balance

In examining the CEMA countries' efforts to improve their balance of payment, it becomes apparent that the decrease in deficit came about in every country as a result of reducing domestic demand and economic growth. The years 1978 and 1979 saw the slowest growth of the CEMA countries. More limited investments and a more moderate increase in production and demand made it possible to increase imports slower and exports faster. This was, by the way, dynamically promoted by the economic management of the individual countries. No matter how extensively the resources for limiting imports and expanding exports could be mobilized, this in itself cannot solve the problems of balance for an extended period. The "boom policy" means of growth decrease or increase (also including the various prohibitions and limitations that are directly related to the sphere of circulation) may be suitable for one or two years as a countermeasure for the tipping balance resulting from a boom (worsening terms of trade and market conditions), but cannot fully compensate for a lack of structural balance which the CEMA countries have had to face since the mid-1970s. And if, as a result of a lack of external balance, production and consumption would fall back--or even decrease--this could lead to problems in the domestic economy and to an increased lack of market balance. And, under these circumstances, it would be even more difficult to stop, or control, the lack of external balance--as the events in Poland also show.

Thus the future of East-West trade, approached from the viewpoint of the CEMA countries' economic policies, depends on the elimination of the causes which make the lack of balance structural, i.e., their export-increasing capacity in the long run lags behind the expansion pace of their needs. The causes, which have been frequently mentioned in Hungary, too, at the debates on the paths of economic policy to be followed and on the mechanism which makes possible to increase efficient exports are complex and extensive. But they are closely connected to the fact that the CEMA strategy of economic development and cooperation is still not permanently free of a CEMA autarky policy or efforts to achieve regional self-sufficiency. The goal is still being proclaimed that all products needed by the

CEMA countries must be produced by themselves. Thus, they must consider the decrease in imports from the West not only as a short-term "tactical" necessity but also as a long-range policy.

But it is entirely clear today that this effort is outdated and impossible to realize: the policy of regional self-sufficiency would not only unfavorably influence socio-economic development in the CEMA-countries, but it is impossible to implement it as well. This follows, among other things, from the cooperation which is characterized by a more protracted and more extensive shortages of goods resulting from a rearrangement of terms of trade. For this reason, the individual countries must acquire an increasing part of their import needs from without the CEMA. This follows from the difficulties which are related to an increasing use of the economic development's "intensive" resources. And they make us more and more aware that continuous and large-scale imports of modern machines and equipment, obtaining technical, technological and organizational information, and the establishment of an attitude of efficiency and innovation are indispensable requisites for scientific-technological development, higher efficiency and higher living standards.

A Long-Range Program is Needed

The consequences of internal processes are connected with requirements resulting from world economic development. Dynamic technical-developmental changes of production structure are continuing to take place in world economy. All of this requires, more than ever, that every country which does not wish to lag behind economic and technological development, take part in the global division of labor—a participation that is dynamic, extensive and partly different than before. In order to make export orientation more than a system of short and middle-range measures that do not change the conditions of economic operations essentially, the int-nsive participation in world economy must be formulated as a long-range program, a strategy of socio-economic development.

All of this means in today's intensified foreign economy [fesritett kulgazdasagi helyzet] that the CEMA-countries must continue to implement import policies which are cautious and circumspect, which carefully consider the macro-economic limitations, which do not hinder a continuous and efficient economy, which guarantee an adequate supply of goods to the population, and which serve longer-range developmental goals better than today's policies. Import policies are necessarily related to the CEMA-countries' possibilities of acquiring credit. The most recent developments in East-West economic relations (including conceptions, still embryonic, regarding existing and further credits offered to Poland) show that the Western countries are continuing to have an interest in developing financial and trade relations with the CEMA-countries. This means that, although the external conditions of such import policies cannot be considered easy, they can be implemented if tensions in international relationships can be avoided.

ECONOMIC REGULATION CHANGES DICUSSED IN INTERVIEW

Budapest NEPSZAVA in Hungarian 7 Nov 80 p 5

[Interview with Miklos Pulai, deputy chairman of the National Planning Office, by James Najda]

> [Text] On the basis of a report presented by the chairman of the National Planning Office, the government approved the proposals for modifying the economic regulators as of 1 January 1981. The government instructed the ministers and national agency chiefs concerned to draft and promulgate the necessary statutory provisions. We interviewed Miklos Pulai, deputy chairman of the National Planning Office, on how to sum up the nature and objectives of these modifications

[Question] Much is being said these days about the economic regulators. On the one hand the reader gains the impression that they are some sort of "mythical" automatism that solves everything by itself, without human intervention. On the other hand enterprise managers complain that changes in the regulators are all too frequent, making it impossible to plan farther ahead and to develop an enterprise strategy. Would you care to comment on this?

[Answer] It will be useful to clarify that the system of regulators is only one element of the system for managing the economy. In addition to the system of regulators, also the national economic plan and the organizational system of management are important components. Moreover, quite a few forms of the management mechanism function as parts of economic regulation: price regulation, credit policy, the system of taxes and subsidies. No less important are personnel work at the enterprises, wage policy, and the various labor-law regulations that rely very much on the individual and provide incentives for workers in various assignments. Thus the mentioned system of economic regulation is by no means omnipotent, nor is its effect divorced from the work, thinking and aspirations of individuals. Concerning the second part of your question: amidst the economy's complex system of conditions and its dynamic changes, it is difficult to imagine a regulation mechanism that is permanent and unalterable, yet always acts in the desired direction. Despite the unavoidable major or minor corrections, we are striving to keep

as permanent as possible the fundamental nature of regulation, its conformity to the norms, so that the economic units may plan with more or less certainty, at least for the intermediate term. I would like to emphasize that this is also my personal opinion.

[Question] The regulators will nevertheless undergo modification as of 1 January 1981. Why and to what extent are they being modified?

[Answer] Actually we are talking about the correction of some elements of the present regulators. These corrections have become necessary for several reasons. At the time of the 1 January 1980 changes in the system of regulation, and of the price system in particular, we already anticipated that certain adjustments and corrections would have to be made eventually, on the basis of practical experience. Actually we are talking about correcting errors--for example, in the case of the starting prices and the base of the wage-development indicator--and about adapting to changes in the conditions of the world market. However, it has become necessary to regulate also the demand for investments. Lately the investment equilibrium has improved somewhat, and it would not be good if next year this trend were to shift again toward unfavorable. The more so because this would further increase the already heavy burden of budgetary expenditures. I wish to emphasize that there will be no basic change in the conditions of economic activity as compared with the system of regulation introduced this year, and we will merely be tightening the requirements here and there, in order to realize more consistently the objectives of economic policy.

I would now like to call attention to some of the changes that must be introduced in the price mechanism, in the regulation of enterprise incomes, in wage regulation and incentives, in technical development and in agriculture.

[Question] We obviously should not think of consumer prices in this context.

[Answer] Of course not. It will be remembered that in their producer prices the enterprises employing competitive pricing cannot include more profit than what is included in the world-market prices of the products these enterprises export. Some domestic enterprises, however, have not complied with the regulations, and it is necessary to assert the rule that the domestic price--on average for the year--may not exceed the export price. The purpose of this is to encourage the enterprises in improving their operations, through the efficiency of export. Investigations show that most enterprises--including the over 30 engineering enterprises where the profitability of domestic trade and the profitability of export still differ today--will eventually be able to follow the export prices, by observing the regulations on pricing. At a few enterprise, however, it is warrented to make certain corrections in the interest of supporting the

modernization of production, and to extend the time limit by which the domestic and the export price and profit levels must be identical, which in most cases involves a reduction of the producer prices.

In those areas where competitive pricing does not apply, the government is likewise encouraging the economic units to conserve energy and raw materials. The various instruments of regulation attempt to prevent the enterprises, for example, from passing on automatically in the prices of their products the higher costs of energy. This forces the enterprises to seek instead methods for the more efficient use of energy.

[Question] You mentioned that some elements of income regulation and wage regulation will be modified. Why is this necessary?

[Answer] The reduction of domestic consumption--or more accurately, of the accumulation-related expenditures--envisaged in the national economic plan, and the greater effectiveness of regulation warrant these measures. Otherwise the basic principles of wage regulation and income regulation will not change. The correction merely attempts to boost their incentive effect, to assert more decisively than up to now the requirements of performance.

The rate of the municipal and community contribution will increase from 10 to 15 percent. Simultaneously, in order to maintain the level of social services at the enterprises, the per capita allocation to the welfare and cultural fund is being increased from 950 forints this year to 1000 forints next year. In other words, this will be the compulsory allocation to the welfare and cultural fund (the number of workers times 1000 forints). Spending from this fund in any given year may be less than the allocation, in accordance with the needs. During the drafting of the modifications, there were differences of opinion concerning compulsory allocation, but finally the standpoint of the SZOT [National Council of Trade Unions] representative was adopted.

[Question] The measures related to wage regulation will affect everyone directly. We know that a spectacular rise in the standard of living would not be feasible now. But anyone who does outstanding work deserves above-average financial recognition.

[Answer] So far as wage regulation is concerned, this is the very reason why we did not wish to restrict wage increases commensurate with a rise in performance. On the other hand, any possibility to increase wages that is not supported by more-effective work must be prevented. The centrally determined possibilities for wage increases, and the 1980 values of the multipliers associated with wage regulation based on performance must be retained also in 1981. In economic activity next year the regulation will apply that the available payroll budget must be used if the decline of the wage-development indicator does not exceed 10 percent. From wage reserves, however, an amount may be used that is needed to raise the wage level by a maximum of 3 percent, over and above the wage increases that may be granted

on the basis of the results of operations in the current year. (A larger amount of the wage reserves may be used only if the wage-development indicator does not rise or declines. In such cases the wage reserves may be used for a rise of up to 4 percent in the wage level.)

They say that wage regulation is not advantageous for profitable enterprises. The exact opposite is true. If the indicator of wage development supports a rise of average wages, the enterprise will not be taxed for a rise of up to 9 percent in the wage level, as compared with a 6-percent rise previously. In other words, the curb on efficient enterprises begins only above 9 percent, which is about 1.5 times the planned increase in average wages.

In financial incentives for top managers, in 1981 the upper limit on bonuses based on comprehensive evaluation must be made independent of the given enterprise's category. The maximum bonus is uniformly 20 percent of the annual salary. In my opinion, the fact that the managers of small enterprises are not treated less favorably than the managers of large enterprises will provide a proper incentive, while this limit on the maximum bonuses that may be paid does not violate society's sense of fairness.

[Question] What changes can be anticipated in agriculture?

[Answer] It is obvious that under the Sixth Five-Year Plan less investment aid can be provided also in agriculture than in years past. Therefore the resources for development must be used more effectively than at present. The new system for financing investments must provide incentives for more-complete utilization of the available resources, and for investments that offer a high rate of return and are best suited for the specific conditions of the individual farms. Knowing these basic principles, the farms next year will be able to undertake capital construction--with the exception of facilities for dairy farming and hog production--only from their own resources or from credit obtained at favorable rates. This is the essence of the changes in agriculture.

[Question] Most of the corrections in the regulators could be summed up in everyday language as belt-tightening. The necessity of balancing the budget, and of improving the external economy's equilibrium, makes these measures understandable. But will they not curb entrepreneurial initiative specifically at the enterprises (and in the sectors) where there are prospects for rapid growth?

[Answer] Since the modification of the regulators will affect the sphere of production rather than the sphere of consumption, instead of your analogy of belt-tightening I would say that economic pressure is increasing on a certain group of enterprises. In any case the objective is to uncover the reserves still existing in economic activity, and to employ more-uniform criteria in evaluating the enterprises. Most of the measures in question are of a comprehensive nature. They do not allow individual

exceptions and tighten somewhat the requirements. The economic units that are able to operate successfully even under such conditions have and will continue to have a bright future. I feel that this is what will continue to stimulate the best enterprises, and this is what we are striving to achieve with the effects of the regulators.

TASKS OF FOOD INDUSTRY REVIEWED IN VIEW OF NEW REGULATIONS

Budapest ELELMEZESI IPAR in Hungarian No 10, 80 pp 364-368

[Article by Balint Balogh, department head, Ministry of Agriculture and Food Industry: "Situation and Tasks of the Food Industry in View of the New Regulation"]

[Text] Summary

The system of economic regulators which will be valid on 1 January 1980 will place greater requirements on the enterprises than before. The profit content of food has declined. In the distribution ratio for profits between the state and enterprises, the change in the revenue regulation system has resulted in a shift in favor of the budget. The enterprise incentive funds that can be formed have also been moderated by the increase in the centralized ratio of amortization. The financing system for variable assets has been changed significantly, a condition of increase in personal income.

A growth in the incentives for food industry enterprises gives grounds for an examination and modification of the extent of the regulators.

Situation and Tasks of the Food Industry in View of the New Regulation

The share of the food industry in the gross production value of socialist industry comes to about 18 percent, and its net production value 7 percent. To fulfill this task, it takes up approximately 12 percent of the producer fixed assets and manpower of socialist industry. The basic task of the food industry is to meet the domestic food demand in quantity, range and quality. Together with restaurant consumption, the branch shares in about 45 percent of the domestic trade, but in addition it also has an extremely important export task to fulfill. The food industry provides more than 10 percent of ruble-account exports, and almost one-third of nonruble-account exports. These ratios make us aware that we cannot be indifferent to how the economic regulators serve realization of the planned economic political goals in the targeting of which the effects of the regulator system must also be taken into account.

Experiences With the Operation of the Regulator System in the Fifth Five-Year Plan Period

Affirming the characteristics of the branch, the regulator system which was developed for the Fifth Five-Year Plan period included many variations from the

general industrial regulator system (the withholding of a part of the general profit tax and 100 percent of the amortization for development goals, direct budgetary support of investments, and so forth).

To a great extent this regulation promoted the creation of the financial conditions for independent enterprise management and particularly the realization of these plan goals:

--along with a relatively rapid growth in consumption, the further improvement of the equilibrium situation on the consumer market and a better satisfaction of demand;

--the increase of exports, including primarily nonruble account exports;

--the creation of new processing capacities which are designed

--to increase commodities that are economically salable on all markets,

--to reduce tensions between agricultural production and food-processing capacity.

However, the growth of production efficiency and the development of a more economic production and marketing structure was less favorable than expected. In addition to the shortcomings of enterprise management, an important role was also played by the unfavorable development, for the enterprises, of the conditions for foreign market activity. (This was also contributed to by the fact that the net income per 100 forints of resources and per 1 worker came to scarcely somewhat more than one-third of the average for the socialist industry.)

In the interest of improving the budgetary balance situation and limiting investment purchasing power, the regulator system was modified a number of times, which has caused problems in the elapsed period of the Fifth Five-Year Plan; and these modifications will also have an effect on the Sixth Five-Year Plan. The problem became evident, and is still present in this form, in that on the basis of the regulatory conditions as shaped for the Fifth Five-Year Plan the enterprises undertook important financial obligations (accepted credits) for the repayment of which the necessary resources following the modification of regulators are not available, or are available only in part despite the quantitative increase in production.

Beyond the question of fulfilling existing obligations, this circumstance hinders the unconditionally justified and necessary supplementing of fixed assets, maintaining of level and assuring the earlier level of personal incentive.

The Goal of Developing the Regulator System

The basic economic political goal of modifying the 1 January 1980 regulator system may be summarized in the following. The new system should promote more intensely than before:

--an improvement in the equilibrium situation of the economy (consumption, savings, foreign trade, and so forth);

--an increase in production efficiency;

--the development of a more economic production or marketing structure to provide a basis for fulfilling equilibrium and efficiency requirements.

The goal of modifying the regulator system basically also defines the possible direction of the modifications because there was no way to carry through such measures as would have intensified enterprise incentive by means of an increase in profits or incentive funds. With the further development of the 1980 regulator system, the enterprises will have to fulfill higher requirements. This is particularly true of the food industry enterprises since as a consequence of the elimination or reduction of the formerly valid subsidies the normative strengthening of the regulation (elimination of general profit tax withholding, moderation of the withholding of amortization, and so forth) has resulted in a greater strictness than average for the regulator system of the branch.

The Enterprise Revenue Regulation System

The system and extent of revenue regulation on one hand determine to a great degree the revenue due to the state from the enterprises, and on the other hand the enterprises' available financial sources for personal income, for increasing personal income, and for development goals. The modification of the 1 January 1980 revenue regulation system had a two-way effect on the share and development funds that enterprises can form. The town and village contribution rose from 6 percent to 10 percent of the rpofit serving as the accounting base, the incentive; and the general profit tax rose from 40 percent to 45 percent of the tax base), and the elimination of the general profit tax for development purposes (18 percent in 1979) reduced the ratio of profit usable to form enterprise incentive funds. At the same time, the reduction of the extent of forming the required enterprise reserve fund (from 25 percent to 15 percent) increased the ratio of the usable sharing and development fund. The effect of these changes on the branch as a whole is reviewed in the accompanying table.

Key:

1. Designation
2. Ratio of profit use
3. 1979 regulation
4. According to 1 January 1980
5. In percent
6. Profit serving as accounting base (incentive)
7. Town and village contribution
8. General profit tax
9. Progressive profit tax
10. Ratio of profit centralization
11. Required enterprise reserve fund
12. Sharing fund
13. Total development fund
14. From the development fund
15. From withholding the general profit tax
16. From the profit
17. Ratio of profit remaining with the enterprise

In summary, the following may be stated:

--the profit distribution share has been altered by 14.2 percentage points to the advantage of the state;

--the ratio of profits that can be used by the enterprises (for the formation of share and development funds) has been reduced by 7.5 percentage points;

--in the case of the formation of the same wage-ratio sharing fund, the progressive tax increases are a result of the fact that the progression of the tax is influenced as of 1 January 1980 by the capital wage ratio profitability level beyond the annual wage ratio.

In addition to the foregoing, we also need to emphasize the following in regard to the change in the income regulation system.

--In shaping the producer price for food industry prices, an average profit of 4.2 percent according to capital-wage ratio for the branch could be taken into account, and by sub-branch the profit varied from 3 to 5 percent. In view of the fact that the basis for developing the producer prices was shaped by 1977 actual figures, let us assume that the 1980 profitability of the branch developed at a capital-wage ratio of about 6 percent as a consequence of the quantitative increase in production and the improvement in efficiency, and the more profitable export than average for certain branches. With a significant spread in the sub-branches, the 1980 enterprise plans called for an average profitability level of 6.6 percent. As compared to previous years, this profitability level represents a substantial drop (12.1 percent in 1977, 8.3 percent in 1978, and 7.4 percent in 1979), and thus in addition to the increase in the centralized ratio of profit, the decline in the profitability level reduces the formation possibilities in the enterprise sharing and development fund both in the absolute and the relative extent.

We also need to note than among the industrial branches the profitability level is the lowest in the food industry. The increase in enterprise incentive, the development of sub-branch profitability ratios more adequately expressing the efficiency of production, and the factoring in of costs already incurred and expected makes it necessary to investigate and increase the profit level of certain sub-branches (for example, the milk, beer, spirits industry, and so forth).

--The premiums and awards of workers in the higher managerial positions were charged to the wage bill until the end of 1979, while, since 1 January 1980, the source thereof has been the taxed profit. The goal of the modification is to assure that only the profitable enterprises have the possibility of paying premiums and awards.

--The enterprises themselves continue to make their own decisions regarding profit use by taking into account legal limits and the orientation effect of the tax system. Because of the large-scale obligations undertaken under the Fifth Five-Year Plan, however, the compulsory priorities for profit use limit to a substantially greater extent the decision-making possibilities of the enterprises. (But the only change that was made in the priorities for using the development fund was that the replenishing of the variable fund precedes the fulfillment of obligations vis-a-vis other enterprises and organs. Because of the priority obligation for development fund formation, an important share of the enterprises will not be able to form sharing funds unless measures are taken for rephasing the obligations. This tension can be further increased by the elimination of the subsidy which until 31 December 1979 made it possible for profitable enterprises to form a sharing fund equal to 6 days' wages before all obligations.

--Many factors limit in the food industry the consistent realization of a profit incentive system. For example, the price for materials and semi-finished products used in the food industry belong to the free form. The anticipated effects of these price-level increases can be moderated only by an increase in production efficiency, but their full extent cannot be countered. At the same time the preponderant share of consumer prices for foods are official prices, which make it impossible to pass on the cost increases. Similar problems are also evident in the field of export marketing (primarily in ruble-account export).

Taking into account the low profitability level of the branch, particularly the sub-branches, and the fact that exports represent an extremely important share of the production in certain sub-branches, the problem should be settled.

--The regulation modifications or the change in prescriptions regarding the use of the obligatory reserve fund create better conditions for a more flexible risk undertaking.

Since 1 January 1980 the obligatory reserve fund has filled a profit balancing function, and in the case of a profit decline can be used for supplementing the incentive funds, up to the previous year's level, with obligation to repay. But considering the circumstance that an important share of the reserve fund which has been formed thus far was utilized without obligation to repay the enterprises must strive, in the interest of creating secure enterprise management conditions, for the formation of a separate fund which can be shaped and used according to their own decisions.

It may be stated on the basis of the foregoing that the modification of the regulation, as opposed to the regulation that was developed in the Fifth Five-Year Plan period, has resulted on one hand in reducing the ratio of profit and on the other hand the ratio of the sharing and development fund formed from the profit. The planned rate of increase in personal income and the provision of sources for the most necessary investment call for an increase in production efficiency. It is necessary, therefore, that profitability should receive a greater role in enterprise decisions. The 1 January 1980 price change resulted in a further increase in the

material ratio of food production. Material costs make up 80 to 90 percent of total production costs. We cannot realistically count on a decline in the acquisition prices of raw materials of agricultural origin. The price and cost relations of agricultural production and the anticipated cost increases do not make this possible, and this has resulted in a production decrease. Instead we need enterprise measures that will make possible a material yield increase through an improvement in the quality of agricultural products, and an improvement in the quality of finished products. This task makes it necessary to increase the purchase of raw materials according to their quality, making production and purchasing work more organized, and to reduce storing and processing losses.

Economic regulation stimulates or compels enterprises to modernize the production structure or to speed up transformation. Without this, not only increased profitability but also its maintenance on level represents a task that is difficult to carry out considering the degressive nature of the modernization supports that can be temporarily extended to production. The most important directions in the transformation of the production structure may be the following:

--increased production of modern, economically produced products that are competitive on the world market;

--reduction or elimination of products that are not modern and cannot be economically produced;

--wide-scale application of more modern production procedures;

--an economic increase in the degree of raw material processing;

--an increase in the flexibility and adjustment capability of production;

--a complex processing of raw materials, and the utilization of by-products and waste.

In addition to all these things, it is necessary to increase the price level of our export products by intensifying the mutual incentives of the producer and foreign trade enterprises as well as foreign trade price work.

An increase in production efficiency, moreover, calls for an improvement in personnel and wage management, an increase in the ratio of wages tied to accomplishment, an intensification of the managing independence of enterprises and factory units, and the modernization of internal accounting and incentive systems.

The Incentive System of Trust Enterprises

Enterprises operating under the guidance of a trust are classified as one enterprise from the viewpoint of profit taxation, incentive fund formation and consumption. Trust-level accounting is justified by the fact that the technical and technological level of the individual enterprises and the production structure are divergent, and all these circumstances result in a significant spread in the profitability of individual enterprises. Moreover, this accounting system promotes the realization of industrial branch developments, the provision of the money sources necessary for the fulfillment of obligations undertaken at the trust level, and the fulfillment of export tasks that fall on the industrial branch. (The

export marketing prices are distributed by main relations, and within main relations by relations.) The modification of the economic regulators requires of the trusts and the large enterprises the further development of the internal guidance and incentive system and the realization of the higher requirements in the internal incentive system.

In the development of the incentive system within the trust, the most important principles may be summarized as follows.

—We must see to it that the general economic regulator system developed for the branch is consistently realized in all enterprises under the trust's guidance. The results from the managing and development activities of the trust enterprises must be planned and taken into account primarily according to the general regulator system. The regrouping of results among the enterprises can be carried out only thereafter. The execution causes difficulties above all in the accounting of export receipts since the price of the same product varies by main relation, relation, and even by contract. In such a case it is necessary to handle the accounts by using planned (accounting) prices, and with the difference of the used accounting and actual price it is necessary from time to time to correct the accounts.

--It is justifiable to link the personal and development interests of the trust enterprises, within trust possibilities, to the res-lts of individual enterprises, that is, to changes therein.

--For the fulfillment of obligations undertaken at the trust level, it is necessary to determine ahead of time, generally in the medium-range plan period, the enterprise money sources necessary for the realization of the industrial branch-level development tasks.

--A change in the incentive system within the trust is justified only in case of a modification of the general economic regulation.

--The internal incentive system must promote the economic independence of the enterprises, the increased responsibility for management, and the discovery of reserves in management.

Foreign Trade Regulation

The extent of the price multipliers (commercial exchange rates) serving organically to link the foreign trade and domestic producer prices changed significantly on 1 January 1980, following that also the commercial exchange rate of convertible foreign currencies. By taking into account the combined extent of the presently valid commercial exchange rates, the differential producer sales tax reimbursement, the export support (including the temporarily extendable modernization support of production) and the attainable foreign exchange prices, it can be established that the foreign exchange earnings level of the food industry sub-branches and of the individual product groups and products within the sub-branches is significantly spread out, and exports at the sub-branch level assure a greater enterprise profit than anticipated. In the field of export interest we need to reckon with a two-way problem. A further decline in the commercial exchange rate of convertible foreign currencies can significantly reduce export price receipts. To reduce or counter the effect, the enterprises must strive to increase export marketing prices. Assuming that the effect of the exchange rate reduction can be countered by a price increase, the expected cost factoring-in, however, can

result in a decline in export incentive. Careful attention thereto or incentive assurance must form the continuous task of the guiding organs.

An increase in economy requires the enterprises to improve the production or the marketing structure.

The Regulation of Investments

The nonrepayable budgetary allotments for new investments starting on 1 January 1980 can be granted only in extremely justifiable or exceptional cases. As a consequence, enterprise investment possibilities are determined above all by the formation of their own development sources. The enterprises can receive state support for investments only by indirect means (state loans), the amortization of which, in case of fulfillment of the profit expected from the investment, can be paid from the profits reduced by the town and village contributions and from the portion over and above the replacement needs.

For outstandingly profitable investments, exceeding 15 percent by capital ratio, the enterprises may share in basic state allotments for which they must pay 15 percent interest over a 10-year period which can be charged to profit reduced by the town-village contribution.

The condition for utilization of the investment credit is that the investment must reach a minimal profitability level of 8 percent by capital ratio. In view of the fact that for enterprise investments beginning after 1 January 1980 a special reserve must be planned and formed as a part of the development cost prescription, the capital ratio profitability level must be calculated after adding the development costs to the reserves.

If the implementation period of the enterprise investment exceeds 36 months, investment credit and state support cannot be extended. As of 1 January 1981 the investment tax and the construction-fitting task will be terminated. Basically two problems are evident in the field of investment activity. Because of the decline in profits and the change in regulators, the branch-profit development fund has been moderated, which is a further hardship on one hand because of the termination of the amortization withholding subsidy, and on the other hand because of the large-scale obligations undertaken for investments realized in the Fifth Five-Year Plan period.

In 1979 the food industry enterprises could withhold on the average 94 percent of the accounted amortization, and 72 percent beginning on 1 January 1980. The amortization that can be withheld in the Sixth Five-Year Plan period to repay obligations charged to the development fund, included the replenishment of the variable fund because of permanent inventory increases, will not provide cover either, and thus the development fund which is formed in the profit branch cannot be used for investment goals. Obligations of this extent are resulting in large-scale reduction of enterprise credit worthiness.

In the interest of establishing harmony between the formation and consumption of the development fund or assuring an unconditionally justified development possibility for individual sub-branches, there will be need in certain sub-branches for measures to increase sources (primarily an increase in amortization withholdings) in addition to examining or rephasing the obligations charged to the development fund.

The Financing System for Variable Assets

The financial system for permanent variable assets was basically changed on 1 January 1980. The most important problems of the modification may be summarized as follows:

--In establishing the replenishment of the variable fund, it is exclusively the value of inventories classified as permanent that are taken into account; other variable assets, the development of stocks for the sources, do not form the basis of replenishment for the variable fund.

--Instead of an increase in the value of inventories for the "minimum" period, the enterprises must finance the value increase of their annual average inventories from their own sources or from medium-term, variable fund credits.

--In case of an increase in the inventory value, at least 50 percent of the increment--or 100 percent in the case of an inventory increase above the plan--must be financed with variable asset replenishments from the development fund.

--In order to moderate inventory fluctuations because of annual variations in the production results of agriculture, the inventory growth in the food industry area may occur on a 3-year "sliding basis."

--That portion of the variable fund which is not necessary for financing permanent inventories can be regrouped in 1981 for investment goals.

A change in the method of financing does not result in the replenishment of the variable fund.

From the foregoing it can be stated that the financing system of the variable assets has become substantially more strict. The tightening occurred simultaneously with the modification of the regulator system, which however moderated the development fund that could be formed both from amortization and profits. In order for a greater share of the development fund to be available in the coming years for investment purposes, the enterprises must pay greater attention than heretofore to the improvement of inventory management, and to the reduction of dispensable and superfluous inventories. The inventory accounting system of the food industry would have resulted in an unjustifiable replenishing of the variable fund in those sub-branches where the inventory value increased between 1977 and 1979, and its financial settlement also occurred. To avoid this now, certain sub-branches have the possibility of accounting the increase in inventory value either with the general industrial or the food industrial inventory accounting system. This solution will be necessary, it can be anticipated, also for the next 2 years. A problem may still arise because of the fact that a favorable, but unplanned, agricultural production result in a given year can cause an inventory increase (for example, of wine, vegetable or fruit) which it is not justifiable to finance fully from self sources. A solution must be found beyond this for the financing of inventory value increases because of expected material price rises, the reevaluation of inventories, and calculating the reevaluation differences.

Earnings Regulation, Personal Incentive

Since 1 January 1980, the wage regulation forms used in the food industry area generally provide the conditions (taking into account also personnel reductions) for a possible wage-level increase under the given conditions.

In examining the earnings regulation system, however, it is necessary to examine certain regulation conditions. This refers primarily to the wage-bill regulation system tied to enterprise achievement.

The most important factors in the general wage-development index are wage cost, amortization, and enterprise results. The possibilities for increasing wage cost are rather limited, and the increase in the value depreciation write-off is limited by the extremely modest development (investment) possibilities. It may be expected that the use of a more flexible price mechanism will, because of the factoring-in costs, result--even in the case of an increase in production efficiency--in a decline in enterprise results in certain sub-branches.

In certain industrial branches the wage development index stimulates an increase in the volume of production. The justification for this is especially debateable in the export-oriented sub-branches since the incentive must be directed primarily at the development of a more economic export structure and an increase in foreign exchange earnings, which is moderated by the use of this wage development index.

In the foregoing I wished to emphasize the most important questions in the modification of the regulator system, the related tasks, and those questions which will need to be analyzed again this year in examining and evaluating the regulator system.

EXPERIENCES WITH NEW PRODUCER PRICES DESCRIBED

Budapest NEPSZABADSAG in Hungarian 29 Oct 80 p 10

[Report by Karoly Kemenes, deputy director-general of the Red October Men's Clothing Factory: "A New Type of Enterprise Pricing: Experiences at the Red October Men's Clothing Factory"]

[Text] Of the new regulations that came in effect this year, the new producer prices had the greatest effect on the enterprises. The new principles of determining producer prices are very different from previous ones. Export-oriented enterprises--such as our enterprise, the Red October Men's Clothing Factory--introduced a so-called competitive price system which follows world market prices. The essence of this is that enterprise pricing is mainly determined by price increases and price profits in non-socialist markets. Domestic prices are also dependent on these factors.

The enterprise can reflect the changes in world market prices in its own domestic prices only to the extent to which it can reflect them in its non-socialist export business. This means--and this is the essence of the change--that the present pricing is not based on cost. If, for example, the cost of a product increased, earlier the enterprise was able to increase domestic prices without any difficulty. Now, however, according to the new pricing regulations, this is only possible when the enterprise is also able to increase its export prices together with the cost increase.

The new economic regulations do not have an effect on the enterprises' primary interest in profits. But they can show profits only if they can increase their export prices on the world market at least as much as--or more than--keeping pace with inflation, and only if they can acquire profits which improve the indexes of exchange earnings. If they cannot attain this, then they cannot pass their increasing costs onto domestic products either.

Associations, Joint Exports

As a consequence of these discernments, our enterprise also had to reassess its management policy. The views at the enterprise had to be changed from many aspects. We offered a course to the effected management and technical executives, informing them about the new statutes, their expected effects and consequences, and developing through a joint effort the views and behavior suitable for the new situation.

Our views on management had to be changed in two ways. On the one hand, we examined our relationship with other enterprises and, on the other hand, we made a critical assessment, within the enterprise, of earlier methods.

A new type of closer relationship with the foreign trade enterprise was a requisite for more success on the world market. We created a foreign trade association with our associate enterprises and the Hungarotex. Exporting industrial enterprises and the foreign trade enterprise are its members. The association's objective, in addition to the increase of exports, is the increase of profits. Its means are: a joint market and pricing policy, mutual financial interest, and profit sharing.

The necessity of new types of relationships with textile industrial enterprises is also part of making exports more efficient. We made agreements of joint exporting with several wool industry enterprises, e.g., with the Richards Fine Cloth Factory. In order to increase profitability, we are following fashion trends more closely, we are also accepting the production of smaller orders, and are shortening production time. We are making accounts to each other on a cost basis and are dividing profits in proportion to the added value.

We also examined the system of contracts at our enterprise. To increase price security, we shortened the time periods of delivery contracts.

Within the enterprise, the responsibility and work of the individual departments, as the pricing, the costing, and the acquisition departments has increased. We had to make sure that the various price indexes were accounted and regularly examined. Bookkeeping had to be adapted to account for and follow the changing prices et-.

The World Market of Textiles

The new system of producer prices has been in effect for 10 months. Before mentioning the experiences, we must talk about the economic environment in which the new price system was introduced.

There is a recession on the world market. According to the prognoses, we cannot reckon with any improvement in the near future. The consumption of textiles is stagnating or decreasing on the world market. Buyers on the capitalist market are trying to survive recession by temporarily decreasing their profits or by searching for cheaper sources of acquisition. Consequently, demand is slackening, but the expectations toward the product are increasing. At the same time, competition on the market is also increasing. The developing nations are increasing the capacity of their textile industries, and the volume of their exports on the world market is increasing; they are producing better quality and, thanks to their potential, they can do this at more favorable prices than the European countries.

Our market research, conducted jointly with the foreign trade enterprise, show that the coming years will see a change from a demand for volume to a demand for quality in textile consumption. The demand for both aesthetic and functional characteristics of the products will increase. Consequently, demand will change from mass products to specialized individual products. It can be stated in summary that the textile and clothing industry must meet the increasing demands under more difficult market conditions.

We Are Still Learning

The new system of producer prices has been thus introduced under these economic circumstances. Its effect on our economic life and individual enterprises is still unclear today. The balance of the first 6 months, which could be suitable for an assessment, comprises too short a time period, and it is thus impossible to draw general consequences. We have taken the initial steps but are still studying the system as a whole and its complex effects. This year's unusual and unexpected change in the forint's value in foreign exchange has caused difficulties for us. Unfortunately, we were not able to pass these effects onto export prices right away.

Also, it has not been established yet in practice, what frequency of price changes (of both domestic and export products) is expedient, and how much in advance must the price changes be announced to--or discuss and come to an agreement with--the buyers.

As I mentioned, the foreign trade association has been established, but it can hardly be said that it functions already and that it fulfills the expectations. The association can be characterized today by saying that the member enterprises are mutually dissatisfied with one another. This dissatisfaction may become the basis and stimulus for its more efficient future operation. The ways of this must be found jointly.

Increase of Willingness for Cooperation

There are more and more contracts of cooperation even between manufacturers of ready-made clothing and textile industrial enterprises. Intentions of such discussions and agreements were especially manifest at the recent Budapest International Fair. These cooperative contracts also mean only the beginning. Hungary has a shortage today of fabrics and accessories. The domestic production of fabrics cannot meet the needs of the ready-made clothing industry, and the same is true of accessories.

Our tasks follow from this. Enterprise price production must be further developed. In accordance with the new regulations, we must improve production technology, must increase the operative activity, and must improve organization and cost management within the enterprise. At the same time, relationships of cooperation must be further strengthened with the associate enterprises in order to become more flexible and efficient on the market.

DEVELOPMENT OF CONSUMER PRICES EXAMINED

Budapest FIGYELO in Hungarian No 43, 22 Oct 80 pp 1, 7

[Article by Mihaly Zafir: "Configuration of Consumer Prices"*]

[Text] In the first 8 months of 1980 the consumer price level rose by 11.7 percent compared to the identical period of the previous year. This consumer price index refers to the complete period of the year ending with the designated month. It is a so-called cumulative, revolving figure. (Every new monthly report lengthens the time span by one month. The price index covering the first 7 months was 112.7 percent, to which was added the August monthly price index of 105.1 percent.**)

This Year's Changes and Carry-Over Effects

The index for each month measured against the identical month of the previous year may be reduced to two components: the price changes for the designated year and the carry-over effects from the past year. Let us look, for example, at the index for March of this year compared to March of last year (which, as it happens, was 112.4 percent). Within this there operates, on the one hand, the effect of price changes during this year (March 1980/December 1979=101.9), and on the other hand, the effect of price changes in the past year as well, from March to the end of the year (December 1979/March 1979=110.5). This denotes the carry-over effect from 1979. The two influences together shape the consumer price index measured against the identical period of the preceding year.

The following table contains the month by month individual price indices as well as the cumulative figures for January-July and January-August. Both effects may be studied from the table.

---

*Prepared with the aid of a report of the Central Statistical Office entitled "Change in consumer prices among the main strata of the population in 1979 and months I-IV of 1980 (September 1980)."

**We can verify by a simple calculation that the January-August index is indeed 111.7 percent, thusly: (7. 112.7+1. 105.1)/(7+1)=111.7. (Naturally, the result is the same if we average the eight-part monthly index.)

Table I. Consumer Price Configuration
[identical period of preceding year=100 percent]

	I.	II.	III.	IV.	V.	VI.	VII.	I-VII.	VIII.	I-VIII.
Consumer price index	117.6	111.9	112.4	113.7	113.5	113.6	112.0	112.7	105.1	111.7
of this:										
effect of the 1980 price change	100.6	100.8	101.9	102.7	102.6	102.9	103.3	102.1	103.1	102.2
carry-over effect from 1979	112.0	111.1	110.5	111.0	110.9	110.7	108.7	110.6	102.0	109.5

As an effect of the 1980 price changes, the August index registers a 3.1 percent price increase: the increase in prices since the beginning of the year contributed by this amount to the fact that in August the consumer price level was 5.1 percent higher than in August of the past year. We should conceive of this in the following way: the price level increased from month to month to a greater or lesser degree--moreover, there were two months when it fell minimally--and thus in the end it was 3.1 percent higher in August than at the beginning of the year (more precisely, than in December of the past year). These monthly indices concluding with August are averaged in the 102.2 percent price index figuring in the preceding table.

As far as the carry-over effect from 1979 is concerned, we see an index in August that differs qualitatively from the preceding months: an index of merely 102 percent as opposed to indices of 110 and even higher for the preceding months. Last year on July 23 the prices of meat, bread and other foodstuffs, and household energy carriers rose markedly. Thus right up until July 23 on the 1979 base the low prices are still in opposition to the high prices operative in 1980, and for this reason the index showing the carry-over effect is understandably high. And since after the 23rd of July these prices are identical in 1979 and 1980, the index of the carry-over effect from 1979 therefore declines from indices of over 110 to 102 percent in August. Why not precisely 100 percent? For the simple reason that last year price increases occurred not only on July 23, but continuously during the year, and the effect of these also carries over.

The actual substance of the table is summarized in the first line: the August price index declined markedly for the reasons already discussed. As a consequence the revolving index also decreased by a full percentage point within one month.

The "Timetable" of the Price Trends

On the basis of a study of the data in the table, several interesting conclusions may be drawn about the price trends of the preceding period, embracing the greater part of the year, about its components, and also about the size of the consumer price index anticipated for the entire year.

1980 has been the year price setting was determined by foreign price developments and when the 1 January price changes based on this were introduced. It is understandable that great interest and expectations surround the consequences of this. It is also understandable that this year they are carefully examining the process determining price developments. We will get an answer to this question when we measure the price level not only against the identical period of the previous

year--as is generally customary--but also note the changes from month to month compared to the previous month.

The origin of the price changes that occurred during 1980 is multi-faceted: wide-ranging producer price changes occurred on 1 January; enterprise starting prices shaped up from calculations made amidst new conditions; these prices were implemented after the temporary price freeze and the process of changing them began in which the consequences of the foreign trade price setting and of the enterprises' own decisions were reflected; and state intervention was put forcefully into operation. The enterprises calculated higher base prices than planned, and budgetary turnover-tax decreases and supplementary consumer price increases to a large extent neutralized the unfavorable impact of this on consumer prices. Besides this, changes in various officially established prices also occurred (for example, a decrease in the price of coffee and stockings, an increase in the price of fuels); the prices of seasonal commodities also increased during the year.

The report of the Central Statistical Office already cited characterizes this process up to May in the following way:

"In January--compared to the beginning of the year [sic]--the consumer price level grew by 0.6 percent, essentially in connection with the January 1 consumer price change related to the wholesale reorganization of producer prices:

--there was a decrease in the price of synthetic knit goods and curtains, worsted wool fabrics and men's suits made from these, black-and-white TV sets, certain toys, household plastic items, etc;

--there was an increase in the price of woven and knitted lingerie products, bed linens, leather jackets, electric household appliances, aluminum pots, metal flatware, paints and other products, and in the price level of repair services and goods transport.

In February a small price change occurred: the price level measured against that of the beginning of the year grew from 100.6 percent in January to 100.8 percent, that is, by a total of 0.2 percent.

In March and April the price level measured against the beginning of the year rose further: from the 100.8 percent in March to 101.9 percent in February, that is by 1.1 percent, while it went from 101.9 percent in April to 102.7 percent in March, that is, by a further 0.8 percent. In both months the price level of seasonal foodstuffs rose. The prices of certain durable consumer items increased, and there were also smaller price increases in other categories of goods. On April 1, the prices of fuels were raised.

In May the price of seasonal foodstuffs rose further, coffee became cheaper by 4-5 percent and stockings by 15-20 percent. The overall price level remained at the April level, and was thus 2.5 percent higher than at the beginning of the year."

In order to make the chronology complete--although, like the preceding, by no means absolutely exhaustive--I will add the other months to this.

From June to August the price of seasonal foodstuffs declined. In June fish became more expensive, catering enterprises raised the prices of alcoholic beverages, and in the area of industrial items small-scale-enterprise price increases occurred. All this raised the consumer price level by 0.3 percent, which was thus 2.9 percent higher overall than at the beginning of the year.

In August, along with various price changes that were not significant in their totality, by nature a decrease in the prices of seasonal foodstuffs dominated. The August consumer price level fell below July's by 0.2 percent; thus the price increase was 3.1 percent compared to that of the beginning of the year.

Table II. Price Changes Between January and August of 1980

		Beginning of the Year (December of previous year) = 100	
	Previous month = 100	monthly	average, from beginning of year
January	100.6	100.6	100.6
February	100.2	100.8	100.7
March	101.1	101.9	101.1
April	100.8	102.7	101.6
May	99.9	102.6	101.7
June	100.3	102.9	101.9
July	100.4	103.3	102.1
August	99.8	103.1	102.2

The data from the table summarize the effect of price changes on price level.

We are in the 10th month of the year, when the price trends for months Jan-Aug are quantitatively known and we have the data for September and October. Should considerable price change occur in the remaining months (which is not likely), this would affect only 2 of the 12 months of the year; its effect on the year 1980 would thus be only one/sixth of that which a full year would have, while five-sixth would carry over to 1981. At this time it is already possible to calculate with a fair amount of accuracy the size of the anticipated consumer price index for the entire year.

The anticipated price index is also important now for two reasons: on the one hand, because the January-August price index was still nearly 112 percent, whereas the 1980 national economic plan projects a price index of only 109 percent; on the other hand, because according to the annual plan the real income of the population must remain at the 1979 level, under the influence of a 9 percent nominal growth and a 9 percent rise in consumer prices. According to observations to date there will be no surprises in the nominal growth, and thus maintaining the level of real income essentially depends on consumer price trends.

We can get a picture of the anticipated price index if we estimate this year's effect and of the carry-over effect on further trends. We have to return to our

first table for this. Starting with the August data we may project the price index anticipated for the remaining months.

The index of the effect of the 1980 price changes will rise further from the 103.9 percent index. The anticipated continuation of the process of price changes noted in months January-August, the recently enacted price increases of certain printing products and wines, the increase in the price of enamel utensils and other items announced for October 1, and similar events will raise the price level. If we project the data for the following months on the line entitled "effect of the 1980 price changes" in the first table, larger numbers will appear there compared to the 103.1 of August. For December even a number close to 105 may be conceivable. On the following line which shows the carry-over effect from 1979, the numbers are continually declining compared to the 102 of August, while in December exactly 100 percent may be found. (This is obvious, for the effect from last December's price changes do not carry over to December of this year; this December's prices can only diverge from those of last December if they changed during the course of this year.)

Considering both effects together, a consumer price index of the order of magnitude of 105 percent (or rather somewhat below this) will be characteristic in the remaining months of the year. Thus in every month the cumulative index will be smaller and smaller. This process receives special emphasis, still, because the population always buys more in the last months of the year than at other times, and thus indices of the lower order of magnitude of 105 percent will operate with greater weight than the time-proportioned ones. Therefore, with regard to the whole year a consumer price index identical with the planned 109 percent or perhaps exceeding this by a few tenths of a percent may be anticipated.

COUNTRY RICHER IN NATURAL RESOURCES THAN ASSUMED

Budapest ELET ES IRODALOM in Hungarian 25 Oct 80 p 7

[Interview with Dr Peter Mach, docent at University of Pecs, by Erzsebet Hallama: "A Country Poor in Raw Materials? A Conversation About Our Mineral Wealth"; date and place not given]

> [Text] Dr Peter Mach, docent in the faculty of economics at the University of Pecs, has been concerned with evaluating and perfecting the system of estimating domestic mineral resources for many years. He also wrote his candidate's thesis on this subject. He has supplemented his earlier diploma in geology with a degree in economics as well; he worked in the mining industry for almost half a decade.

[Question] Why are you particularly interested in the mineral question?

[Answer] Our system for estimating domestic mineral resources is a subjective one. One example: between 1960 and 1970 it was shown by this system that domestic coal resources were not worth developing, and then in the 1970's--by the identical method--the opposite was shown. This system does not give objective, or in other words useful, results. The evaluation is based on world market prices, in particular the purchase price of the given raw material at any moment.

[Question] During the years of abundant and inexpensive oil, coal must not have had a very great value.

[Answer] We can come to a very important idea with the example of oil. It is obvious that the price of oil between 1950 and 1970 was very low; it even decreased while the prices of other products on the world market were progressively rising. The reason for this was that market was dominated and supplied by the large multinational firms which owned the exceptionally cheap Middle-East oil fields that were discovered at that time. These large monopolistic organizations acquired oil at depressed monopoly prices, and the depressed prices served to create the impression of abundance that appeared in the market. The oil fields that were harder to work, that is those producing more expensive oil, were not worked. But when the cheap oil began to run out, it was necessary to begin to work them also. Marx's theory of ground-rent, which is a fundamental law in mining economy as well, took effect: The price is determined by the worst place that is still needed.

[Question] But oil prices would in any case have started upwards even without the statement of the Rome Club and, later, the actions of OPEC.

[Answer] At best they might not have risen so explosively. The other side of the phenomenon is that the production of and search for substitute raw materials stopped or at least slowed down because of the low oil prices. Today it is already clear that the rise in oil prices would have been slower if coal production had not lessened in the meantime.

[Question] So do we err by "giving in" to the temptation of world market prices of the moment? Is that what happened when domestic coal production was reduced?

[Answer] In general we did the same thing as other countries, but slower, too late, and in excess. But I see as the reason for this something else. Let's go back for a moment to Marx: The ground-rent rises with the level of technology, so mineral resources are more valuable the greater the level of technology by which they are produced. With us, because of the low level of technology in coal production, the existing coal reserves were objectively devalued. It would have required serious investments and mechanization to make it worthwhile to produce coal at a time of cheap oil prices. There was also the supposed reason that we "are a country poor in mineral resources." This common belief, which still has effects today, arose from the ideology of the Horthy era, and like so many others, it pointed to a false direction that seemed easier, it has kept itself alive for so many decades that even today it still appears, even in specialist circles.

[Question] What would be the proper method of evaluation?

[Answer] The system of evaluation would have to achieve a triple goal. First: to give information to leaders of the economy for decisions at the level of the national economy. Second: to make available correct background information for enterprise decisions. Third: the evaluation must serve to protect mineral resources and to manage them rationally. The mineral resources are available "for free," and we are presently attempting to protect them with just administrative means. Normative economic regulation forces the enterprises to make economic maneuvers and directs them toward the easiest solution, for example, that they leave in the ground the resources that are more difficult to reach. The theoretical basis of the system of evaluation I am recommending is the "mine rent," with which an evaluation system can and must be formulated that will take into account the peculiarities of mining. Raw materials must be purchased from the enterprises at prices that will cover expenses, and the income from mining enterprises must be devoted to geographic research.

[Question] Are resources being evaluated by this method today?

[Answer] In some places concessions have been made. But as with any mixed solution, these also just hinder and delay a resolution of the question.

[Question] So are we a poor or rich nation in natural resources after all?

[Answer] Neither poor nor rich. We are one of the countries with a good, average supply. Even though, of course, there are some items in which we are

deficient, we have a very good supply of some raw materials: some ores, coal, fissionable materials. Our bauxite resource is of European importance. The recently discovered resources of nonferrous ores are outstanding in Europe. We have a significant amount of anthracite coal, which counts as an increasingly important energy resource. But we don't have enough mineral resources that we could influence world traffic in raw materials and energy to any great degree or that we will be able to export for a long period of time. Of course, this does not mean that we cannot export at all, because we are selling raw materials abroad today--bauxite, manganese ore, gemstones, pearlite, etc, but this is not the right long-range solution.

[Question] The last report of the balance of our national wealth was made in 1976; then the known mineral resources constituted 12 percent of the national wealth.

[Answer] But geographical research had stagnated for many years prior to that. In the last 5 years, on the other hand, we have discovered numerous mineral resource sites; we have more than replenished the amounts of hydrocarbons extracted. All of what I have said about our comparative economy relates to quantity. The quality of mineral wealth is relative to economic evaluation and depends on the level of technology.

[Question] We often hear that mining is a branch that requires a lot of investment.

[Answer] This is not the "fault" of the mineral wealth. For example, the anthracite from Mecsek is one of our greatest resources. The technical level of the Mecsek mines has stagnated for over a decade; even today the Zobak shaft is the most "modern" operation. On the average they are 20 years behind. The enterprise has not been able to realize income from production, since the prices have been set arbitrarily, and in the trust system, excess income in various places, which might have been devoted to industrial development, has been systematically recategorized and taken away. The Mecsek mine can only put an end to this situation if it receives a larger framework for investment. It would seem that Mecsek would be asking for something [new], but in reality they would just be asking for a return for value produced. At the same time, in the present situation, the value of the existing anthracite resource is being reduced.

[Question] In such circumstances, is there any reason to press for development of mining? Don't we have time to wait? Wouldn't it be cheaper to import what we need? Shouldn't we rather develop something that will bring a profit sooner?

[Answer] It is easier to develop a manufacturing industry, and it is seemingly cheaper. But we must participate in the international division of labor in a way that is advantageous to us. What can a country bring to the world market? Modern products of a high technological level which presuppose a large scientific-technical background and experience. Or with traditional, average goods, which can be divided into two groups: capital and labor-intensive products. Finally, with raw materials. In the first case, we can base ourselves on

imported raw materials, even with rising raw material prices, because in the marketplace, the prices of these kinds of goods are rising at fast rates. There are few of these kinds of exports in Hungary. It would require a long time and significant efforts to develop them. But in the other cases, the balance tips. It is not worthwhile to export to the world markets obsolete, or below world standard, average goods produced from expensive imported raw materials. Sooner or later it will be seen that only a manufacturing industry based on domestic raw materials can bring about a solution. Development of agriculture is important, but here too it is necessary that the proportion of imported raw materials (which also appear in the form of energy, machinery, etc!) be reduced to a minimum.

[Question] How does the present organization of industry look from the point of view of the domestic mineral raw material basis?

[Answer] Where we have sufficient tradition and culture, the organization of industry is of course critical. But of the industries based on imported raw materials, it is sufficient to mention the textile industry, whose problems are apparently known by many people from Gyorgy Moldova's book, if from nowhere else. Our chemical industry is also based on imports. Our supply of bauxite, however, is significant, and plans to use it more efficiently have already been made. We are also well supplied with manganese ore, which, however, is only a valuable and important item on the world market in the form of ferro-manganese. Without domestic manufacturing, we would lose the real value of this mineral resource. An industry in nonferrous metals could confidently be introduced, based on the ore from Recsek.

[Question] For example, domestic mining does not even supply one-seventh of the coke we use, even though the raw material is present in the form of anthracite coal that can be made into coke.

[Answer] The rest is imported, and this constitutes an increasing share of our capitalist import. The price of coke is continually increasing, and we can expect a shortage of coke on the world market. The Ministry of Refining and Machine Industry is planning to build a coke plant at Dunaujvaros in 1985. But production of anthracite of Mecsek has fallen by about a half over the years, and in present circumstances there is no way to increase it. But the Ministry of Heavy Industry has not yet decided on investment in the Mecsek coal mines, and even if it does soon, we will be able to produce hardly more than half of the coking coal we need by 1990. But even so, our overall domestic mining would become profitable. And this naturally affects the finished products. At the same time, geographical studies have uncovered the so-called Maza-Deli site for coking coal in addition to the previously known Mecsek source. This is a resource of European significance. If we could work this field with today's most modern technology, the amount of coal produced would be about half again as much as we can achieve with our present technology. If a given amount of investment funds is regarded as just being for mining, it may seem like a lot. But if we project it onto the whole manufacturing industry--and this is not only justified but necessary--mining is no longer a branch that requires too much investment.

[Question] Do we have enough raw materials of the kind that will make possible a selective development of domestic manufacturing industry?

[Answer] Taking into account the possibilities offered by CEMA, with appropriate selection, we could eliminate capitalist imports almost entirely. Presently, almost half of our imports are raw materials or semifinished products. In this situation, even our high-level, traditional branches of industry lose in value. I am convinced that the public has not yet become conscious of the fact that development of industry can and should only be done on the basis of our own raw materials.

COSTLY INPUTS REDUCING PRODUCTION VALUE OF AGRICULTURE

Budapest FIGYELO in Hungarian 29 Oct 80 p 13

[Article by Dr Laszlo Nemeti: "Why Is Production Value not Increasing?"]

[Text] During the Fifth Five-Year Plan agricultural production increases have been achieved through increasingly greater monetary and fixed assets investments. The combined amount of live and passive labor utilized per production unit has increased in the same way. The increase in the material consumption-production ration of agriculture is related to increased chemicalization and energy consumption, as well as to livestock raising's more rapid development than that of crop production, or rather, to the increase in the accompanying fodder consumption.

KEYS:

1. The development of net production value in agriculture
2. Billion forints
3. Large socialist enterprises
4. Small farms

Domestic prices, for the most part attuned to the world market, developed in such a way that the price levels of industrial products and materials utilized in agriculture increased more rapidly than those of agricultural products. This compelled farms and enterprises to be more thrifty and economical in their consumption.

Despite this--as a result of development in production techniques and technology--the proportion of these continued to increase within the total resource consumption. The higher priced, industrial origin products, or rather the increase in the volume and proportion of resource consumption in itself resulted in the net production value's* increasing more slowly than the gross production value.

Increasing Investments

During the Fifth Five-Year Plan, consumption by producers increased by 26 percent. Within this, consumption of industrial origin materials and of energy sources by producers increased by 34 and 36 percent respectively. Moreover, the combined total of fixed assets maintenance and amortization rose by an average of 50 percent during the 50 years.

In 1975, the net content of national production per 100 forints gross was 37.7 forints. In agriculture, the net content was 39.2 forints. By 1979, as a result of shifts in proportions of investments and domestic prices during the last 5 years, the net production value decreased to 35.7 forints in industry, and to 33.6 percent in agriculture.

Agricultural production growth during the Fourth and Fifth Five-Year Plans took place while there were significant decreases in manpower and land under cultivation and large scale increases in resources consumed. The increase in resource consumption exceeded the increases in the quantity and yield of agricultural production (crops, livestock). As a consequence, specific material and resource consumption by producers increased, since the replacement of the cultivated land and the still inexpensive labor can only be realized through expensive implements and industrial materials. For example, a modern sugar beet combine costs more than 4 million forints. This is equivalent to the average annual income of 100 workers. Moreover, the annual amortization cost of the same machine amounts to the average monthly wages of about 200 workers. The costs of modern means of production utilized more and more widely in agriculture are excessively high when compared to the production increases achieved. Thus, during the time period examined, there was a one percent decrease in labor time invested while fixed asset and material investments increased by 1.5 and 1.3 percent respectively. As a result, the combined total of consumed live and passive labor per product unit increased, not decreased.

Also contributing to the deterioration of effectiveness in consumption by producers in agriculture was the fact that during the first half of the seventies, investments and supplementary expenditures increased at a more rapid than the optimum rate. The appropriate production experiences, which can be acquired only through several years of operation, lagged behind the rapidly growing financial-technical basis.

Expensive Substitution

Numerous factors influenced the deterioration of efficiency of resource utilization and material exploitation. For example, while the cultivated area which served as the basis of production was 4.2 percent less in 1977 than in 1975, the expenditure for live labor for agricultural production decreased by 22 percent during the same period. Thus a significant portion of industrial production resources consumed by agriculture replaced the lost cultivated land and manpower.

---

*The net production value is the difference between the gross production value and the sum of the resource expenditures and the decrease in the value of fixed assets; in essence, it represents the contribution of national economy branches and sub-branches to the national income, or rather, to the net national production.

The increase in the proportion of higher level industrial origin production instruments in monetary expenditures has increased the resource requirements. The technical-technological development of crop production was accompanied by wholesale technical changes. The traditional large farm implements were replaced by high performance specialized machinery and machine systems. The technology required new, higher level projects and increasingly larger quantities of traditional and new materials, while the new processes required increasing energy consumption. The development and continued spread of the technology gave rise to the steady multiplication of relatively expensive machinery, equipment and materials. The modern machinery and energy sources, a significant portion of which is derived from imports, are considerably more expensive than the traditional instruments they replaced. Thus the increase in their proportion in itself increased the material and resource requirements of production.

The production increase in agriculture--despite 2 years of poor yields--was significant during the Fifth Five-Year Plan. However, because of the more rapid increase of consumption by producers, the efficiency of the materials consumption of agricultural production deteriorated by nearly 8 percent.

As a result of the increase in the resource requirements of production, the total net production value of agriculture increased by an average of 9.1 percent over the 5 years. Within this, the net production value of agricultural products increased by only 1.7 percent over the average of the previous 5 years, while that of non-basic activities increased by 47.7 percent. On the average over the 5 years, the 3 percent annual increase in the gross production value of agriculture was accompanied 0.3 percent average annual increase in net production.

The nearly 30 percent material consumption increase by crop production was equivalent in quantity to the gross production increase. Thus, on the average, net production during the 5 years hardly changed. It is true, however, that the unfavorable years of 1976 and 1979 also played a role. The effectiveness of material consumption in livestock production during the last 5 years was more favorable than that of crop production. While consumption by producers increased by 21.5 percent, the gross production value increased by 20 percent. In fact, in the last 3 years, the rate of gross production increase has exceeded the consumption by producers, thereby improving effectiveness slightly. This is also indicative of the rising level of farming.

Somewhat Less Than Optimum

The production structure has also shifted towards branches which require more raw materials. The development of more material intensive livestock production is more rapid than that of crop production. The change in proportion which resulted from this increased the material requirements of unit agricultural production by nearly one percent.

The fact that the earlier relatively low energy and raw material prices promoted the wider than justified spread of energy and material requiring technologies has also been detrimental to the effectiveness of material consumption. In addition, moral and monetary incentives motivated the farms primarily towards quantity. Profitability was squeezed into the background.

In some groups of agricultural plants in several important branches, the magnitude of expenditures is not proportionate to their resources.

That we have not exceeded the optimum limits of yield development is indicated by the fact that for more important products the profit is most favorable in farms with the highest yields, and is lowest where the yield is the lowest. In certain branches, however, some farms are producing with a higher expenditure level and some with less, compared to their natural and economic resources. In either case, the effectiveness is less favorable than is possible.

In a portion of the farms--and these include a wide range of those with favorable natural resources--material and monetary problems are making the creation of the monetary assets and supplementary expenditures necessary for achieving optimum yields difficult. In the rest of the farms, however, low directive, professional and organizational levels are the reason for the unfavorable development of the "expenditure yield."

During the Sixth Five-Year Plan, the tendencies of the recent years are expected to continue. Because of scarcities in biological and development resources a smaller quantitative production increase can be expected.

Direct Concern

During the coming period, while increasing the environmental protection of the soil and utilizing the augmenting activity of labor, the productive forces--despite smaller investments--are to be kept at the current level. After the 1980 price adjustments, price differences can no longer be increased; in fact, they ought to be decreased, since the reduction in income is making even the possibility of self-sufficient farming, especially by farms near or under the average level, questionable. With the replacement of state subsidies by the price structure, net production value can be increased to a certain extent.

The production structure development will be better balanced, since the growth rate of livestock production is expected to decrease and the crop production branches which yield a better income will grow more rapidly. The continued rapid growth of supplementary activities can also result in stabilization of enterprise operations and growth in net production value.

The main reserves of the coming period, however, can be the continued rapid increase in productivity and improvement in the economy of materials and resource utilization. But to accomplish this, it is necessary to improve the quality of the materials and instruments utilized by the branches.

There are also large reserves in increasing concern and in improving the organization effort in agricultural plants. However, we can achieve this more rapidly only by differentiated wages and by creating direct interest in production results and materials conservation. Within the plant accounting and the direct interest of the workers can be the greatest boosters of the coming plan period.

Improving the effectiveness of production, however, also demands improving the market position of products, increasing enterprise self-reliance and developing integrating relationships. We can also foster the plant and social success of farming by strengthening our mutual interest relationships.

SURVEY OF DOMESTIC TRADE, SERVICES IN LIGHT OF ADDITIONAL FREE TIME DISCUSSED

Warsaw POLITYKA in Polish No 42, 18 Oct 80 p 8

[Article by Krystyna Zielinska]

[Text] In their instructions to employees formulated in the 1930's, the firm BRACIA JABLKOWSCY (Jablkowski Brothers), which was one of the first modern department stores in Poland, listed 40 points. The final, telling point was the following: "Remember that domestic trade is one of the most important areas leading to the rapid progress of civilization."

Treating domestic trade as one of the essential tools for the development of the collective culture seems particularly important now, at the threshold of 1981, during which year the realm of free time is to expand substantially. In this light, all of the problems linked to recreation, buying groceries and household goods and using food services take on major significance. Two research organizations are even engaged in studying the organization of domestic trade on free Satrudays in an attempt to learn of our weekend preferences in the area of purchasing. Do we buy because we are so fond of our favorite stores and there is nothing which can discourage us about them? Or do we buy because we must, because of the way the family's time is budgeted, because of the way domestic trade is organized during the usual working day, and because of the way stores are supplied?

Is it the case that now, during a period of threatened "market supply," we have a general problem, as, for example, a change in buying habits (it does not matter whether this is a question of choice or of necessity) relative to making purchases on free Saturdays, as well as on Sundays when this is possible?

The research which has been conducted over the past 2 years demonstrates that we spend 1 half-hour more per day shopping than we did in the 1960's, that we shop in more and more stores to buy basic articles, and that we are standing in line for longer periods. This alarming data was to offer proof that the development of the now filmsy network of our retail stores and domestic trade shops is essential. It has. At the same time, however, it should be noted that despite the total impoverishment of the material base of trade, supply is the major problem. Customers are right to be resentful when they are reproached for not planning out their shopping trips, sending their daughter to the store for five eggs and yeast, their son for oil and their husband for flour. It angers merchants when they are made to stay open on Saturday to sell four eggs for someone's noodles and a loaf of day-old bread. Workers of the Bialystok department store CENTRAL went

on strike recently; one of their principal demands was that the store should be closed on Saturday and Sunday. They argued that the weekly turnover at this store is 2.5 million zlotys per day, with Sunday sales totalling 400,000 zlotys, half of which is in vodka sales!

Zofia and Zdzislaw Swietczak, co-managers of the self-service grocery at the SEZAM shopping complex in the heart of the Warsaw business district, point to receipts and the conflicts arising from the fact that their employees must come to work on free Saturdays. Receipts are from 20 to 30 percent smaller, but the conflicts are much greater. At SEZAM, which is an enterprise with broadened authority, workers are paid an extra 200 zlotys for working on Saturday. Theoretically, they are also entitled to a day off. In practice, of 55 people who worked on Saturday, no one has had a chance to take his day off. People do not want the money. They are overtired from coming back and forth to work (most of the work force lives outside of Warsaw). They note that if the store is open from 6:30 am until late in the evening, i.e., 8:30 pm, 5 days a week, and it is adequately supplied with goods, there will be no need to open it on free Saturdays.

Recently I had an opportunity to be persuaded of the strength of the family ties between domestic trade and the factory. Every third or fourth salesgirl or cashier has a husband who works at a large industrial plant. When I broached the subject once on the air during a radio program, I did not have long to wait before the letters, telephone calls and visits to the station started. Representatives of the highly industrialized working class responded immediately; it is easy to guess what tone they took.

Zofia and Tadeusz Szafranski invited me to their home. She works in a large self-service grocery in Bielany, he works at the Warsaw Steel Mill. When I asked who returns home from work more tired, the husband answered--his wife, without a doubt! He said that his job was to sit and oversee the power situation at the plant by keeping watch over the measuring apparatus. When something goes wrong, he makes a call. His room is air-conditioned. So is his wife's place of work--the door to the store never really closes, because of the never-ending line, and it is hot in the summer and drafty in the winter. When she worked at the cashier's booth she became sick with a kidney ailment and for hours she could not leave her post to take care of her bodily needs. Moreover, the worker always leaves the mill on time; the cashier never leaves the store on time.

So I asked whether the wives of the other mill workers would be happy if there were no domestic trade on free Saturdays. He said no.

She said that this was their egoism. Common egoism. So that the store could be constantly at the customer's service.

Waht are the plans of domestic trade at present and what are the possibilities for tempering our commercial "egoism?" The following possibilities (in the form of proposals, not decisions) were presented to me as solutions at the Ministry of Domestic Trade and Services; Keeping grocery stores open of Fridays 2 or even 3 hours longer; Shifting the major burden of purchasing to the final days of the week will necessitate changes in the operation of warehouses, transport and several divisions of food production, such as bakeries and milk processing plants (the latter being very difficult). On free Saturdays, 4,000 grocery stores operating

within a very transitory system will be open. These are large outlets located centrally within larger complexes. The local authorities will determine which these will be. Grocery stores would be open for 4 hours at most on free Saturdays. In large cities stores now open for 24 hours would remain so. In this way, 25 percent of the network of large grocery stores would be open on free Saturdays, and not 50 percent as is now the case, and these stores would be open 2 hours less than they are now. The ministry emphasizes that "The network of stores selected to be open on Saturdays should not be changed within the course of the year, and society should be informed of the addresses of the outlets which are open by means of notices hung at all outlets of a given sector and via the means of mass communication."

The operation of village trade will necessitate a separate regulation. Department stores, which until recently were open on every free Saturday, are to be open every other Saturday according to this same plan.

And now some information about how this situation is handled abroad: in Czechoslovakia all Saturdays were made work-free starting in 1963.

Initially, 80 percent of all grocery stores and 50 percent of all industrial stores were open on Saturday for 2 hours: from 12:00 noon to 2:00 pm. Now the delicatessens (the so-called "Lachutki") are open both on Saturdays and Sundays. On the other hand, industrial stores are closed. Department stores are open from 9:00 am until the afternoon. The grocery stores which were closed on Saturdays immediately following the reform have been open for 6 hours in recent years: now they are open from 6:00 am until 12:00 noon.

In the GDR, free Saturdays were introduced in 1967. Initially, some grocery and industrial outlets were open for 2 hours on these days (from 11:00 am until 1:00 pm. Now all of the so-called "Kaufhalle" and a group of stores selling baked goods and meat which never changes are open for 4 to 5 hours. In the central shopping districts of large cities, some department stores and industrial stores are open from 8:00 am until 1:00 pm. Every fourth Saturday stores are open for the purpose of "family" purchases on these days furniture stores, television repair shops, building supplies stores and clothing and shoe stores are open for several hours.

In Hungary, with the introduction of two free Saturdays per month in 1974, the whole network of grocery stores was open until 7:00 pm. Now these outlets are open only for 4 or 5 hours. Certain select large self-service stores are open from 6:00 am until 4:00 pm. Department stores are open from 10:00 am until 5:00 pm, and some industrial stores are open until 3:00 pm.

To this account may be added a few words about the operation of trade and services in capitalist countries. In London, Saturdays and Sundays are a time of great prosperity for small delicatessens; but in small towns almost all stores are closed. In some quarters of Paris it is possible to buy anything on even the biggest holiday. In Sweden I surveyed the operations of the firm of OBS. On free Saturdays and Sundays people drive to suburban department stores of this firm for major purchases. This is because the OBS stores are both more pleasant and cheaper than other stores. There are 24 automatic cashiers operating at the same time, and since everything comes in the large size (which is cheaper), customers buy twice as much of everything. Additional employees are needed to staff the stores on Saturday, but the firm tries to see that these are kept to a minimum.

An Ilf and Petrov hero says: There is no limit—the limit is a myth." The same may be said here. None of the examples from the West and from our sister countries fit us. By comparison to Czechoslovakia, for example, we have 300,000 fewer people in domestic trade... In none of our neighboring countries does the cashier ring up a sale of 1,000 or 2,000 zlotys every 3 minutes--but in our CENTRUM stores this does happen. People who work in domestic trade are weary. Comparisons of the strenuousness of their work with the work of a metallurgist or a miner do not take into account the tension under which they are working. Does a miner who is not in a position to supply us at this moment with enough coal for heating our house have to look at the waving arms of 60 or 70 people? That many people stand in queues at meat stores, watching and becoming angry. And at the JUNIOR shop, when corduroy pants are brought in, it is even worse than behind the meat counter.

It is apparent that the reform of "trade and free Saturdays" should be carried out in two stages. In the first months of 1981, a very few grocery stores should be put into operation--as it is there is very little of ANYTHING to sell and hardly ANYONE to work, since everyone wants a free day. Trade should not be squeezed out too much by the leveling of constraints and administrative orders on the part of the governors, because then no one will be willing to work in trade. On the other hand, other paths should be sought, and much more energetically than before. Much is being said about the part-time employment of people. Retirees and mothers on maternity leave who would like to return to work were to come to work and stand behind the counter at peak hours and on days of particular need; students were to help (everywhere on earth weekends offer a chance for them to work in trade and food service). What of it. In 1978, total part-time employment was 7.4 percent, in 1979 it grew to 8.5 percent, and in 1980, 10 percent of all those employed are part-time workers. We have lovely plans for 1985; three times as many people will be standing behind the counter, in order to improve the statistics of the flexible forms of employment in trade; we have always had lovely plans for the distant future, and gaps in our intentions for tomorrow. Now it is essential that we fill in these gaps, in the first place, in a very simple way, by eliminating certain absurdities in our system of wages. An English language graduate who is on pension can make 36,000 zlotys a year. But a veteran employee in domestic trade even one with the best qualifications, can receive, at most, 3,000 zlotys per month.

A representative of the Ministry of Labor, Wages and Social Affairs recently said on television that domestic trade workers should work on free Saturdays and should have the day off on Mondays. But this will not happen. Already with only one free Saturday per month, tremendous backlogs in the area of free days have arisen, and there is no time for these free days to be granted. Salesgirls are always working for someone else anyway, because maternity leaves and sick leaves produce many opportunities for this. And the extra 200 zlotys for Saturday work which I mentioned above may be paid only by a few enterprises; a stiff corset of payment restrains the others. Thus, easing strict regulations, increasing the pay scale for free Saturday work, and increasing the possibilities of additional wages for pensioners and other persons outside the profession—all of these seem to be necessary.

The Institute of Labor and Social Affairs is conducting scientific research on the organization of work in domestic trade outlets on free Saturdays. They ask such questions as: When did you learn that there will be a free Saturday?— Did you

rest on your last free Saturday?--Did you leave your place of residence?--Did you buy bread, milk or other items?--In your opinion, is shopping on free Saturdays essential? To this question number 16, found nearly at the end of the survey, most people responded in the following way: "On the 2 days preceding the free Saturday, stores should be supplied in such a way as to allow customers to make all of their essential purchases. A day off from work should be a day of rest."

A survey conducted jointly by the Office of the Wroclaw Voivodship and the City of Wroclaw, and the Center of Market and Consumer Research in 33 factories and enterprises gave the following results:

Of those taking the survey, 79 percent believe that free Saturday purchases should be restricted to basic food items (dairy products and baked goods above all). Nearly 72 percent of those surveyed were in favor of an extension of hours of operation on weekdays, especially with regard to grocery stores. "The operation of domestic trade on free Saturdays in the proposed area"--we read in the summary of the survey--"is treated as a temporary solution. To the extent that the production potential of the food industry develops, enabling the guarantee of increased deliveries on days preceding free Saturdays; to the extent that habits of taking advantage of free Saturdays for rest and recreation become universal in scope, the gradual limitation of trade activity on free Saturdays is assumed. This will make it possible to implement the demand of store employees concerning the possibility of utilizing powers in this area on an equal level with the other divisions of the national economy."

Despite all of this research and these assertions, there is undoubtedly a conflict between social interest and the habits and interest of domestic trade: of its basic work force, its working class, which, like everyone else, would like to rest on free days. The attempts of market organizers, in turn, to extend the workday on Friday are in conflict with the production capacities of bakeries and milk processing plants which work three shifts as it is, their work hours already extended in relation to the market. A weak transport and storage base does not offer complete guarantees either. Thus we must find reserves, perhaps in the organization of work, to reach a solution which will lead to a reasonable compromise.

ROLE OF INCOME, EXPENDITURES BUDGET IN SELF-MANAGEMENT

Bucharest ERA SOCIALISTA in Romanian No 21, 5 Nov 80 pp 5-7

[Article by Dr Radu Ciurileanu, director general in the Ministry of Finance: "The Income and Expense Budget—a Tool for Worker Self-Management"]

> [Text] Nicolae Ceausescu, in a speech at the plenum of the RCP Central Committee on 14-15 October 1980: "It is necessary for us to turn decisively to the steady application of the new economic mechanism in its real sense, setting the whole activity in the economic and social fields on the principle of self-administration and worker self-management. Each unit, of every kind, must know what it produces, what income it has, what it consumes and what it must give to society."

Within the Romanian model of worker self-management, an extremely important role goes to the income and expense budget. The preparation and execution of it have as a goal the more intense use of the economic and financial factors in the activity of the enterprises, the increasing of the responsibility of the staffs of working people and the collective leadership bodies of each socialist unit in the rational management of funds, the raising of economic efficiency, the strengthening of plan and financial discipline, the respecting of socialist legality. "On the basis of the principle of economic and financial self-administration," Comrade Nicolae Ceausescu pointed out at the plenum of the RCP Central Committee in March 1978, "each enterprise and economic unit will have to prepare its own income and expense budget, starting from the necessity of providing, from its own activity, both the financial resources needed and an increase in profitability, in profit."

In our party's view, the income and expense budget is the means which reflects, and by means of which there are applied, the principles of the new economic and financial mechanism, the measures for improvement in management and planning established 2 and $\frac{1}{2}$ years ago. In other words, the role, functions and importance of the income and expense budget of each socialist unit do not come down and are not limited to a document for planning, for analysis and control in the process of executing the plan, that is, to a routine matter in the work of management.

Taking into account the organization of economic and financial activity on the principles of self-management, self-administration and self-financing and the necessity of combining the general interests of society with those of the staffs of working people and of each particular one, the budget is meant to contribute to the

maximization of the economic results through the obtaining of as high profits as possible and high profitability. Occasioning moments of analysis, discussion, choices and decisions, the process of preparing and executing the income and expense budgets mobilizes the staffs of working people to utilize the whole material, financial and human potential, orients the efforts and initiatives in the direction of increasing the economic efficiency, of obtaining a new quality in all economic and social life in our country.

Role and Functions

As it was conceived, the income and expense budget synthesizes, first, the physical structure of the production that the unit will achieve and, at the same time, measures the expenditures that will be made for this production. The entering of incomes and expenses in the budget presupposes the clarification and resolution of a multitude of tasks and problems that involve the entire activity of any socialist unit. If we refer, for example, to the manner of establishing and entering in the budget the receipts from selling the products, this presupposes knowledge of the structure of the physical output and, in correlation, the finding of the ways to use the production capacities as fully as possible, the securing of the contracts on collaboration with the units that participate in achieving the physical output, the matter of completely contracting on schedule for the physical output for the economy's internal needs or for exportation.

Second, the income and expense budget, by its very construction, representing a synthetic picture of the economic activity, offers the possibility of knowing—as early as the phase of conceiving the plan—the level, volume and destination of the profit and thus of establishing the methods of fulfilling the obligations to society and of supplying, within the framework of the self-financing process, one's own funds for development, profit sharing with the working people, various social actions and so on.

Third, the income and expense budget has the mission of offering to the party bodies and organizations, to the collective leadership bodies in the phase of executing the plan a comprehensive picture of the economic activity performed and the results obtained, creating the possibility of channeling the collective efforts of the working people toward the exemplary fulfillment of the plan to all indicators. "We must understand," Comrade Nicolae Ceausescu pointed out at the work conference in the RCP Central Committee in May of this year, "that the income and expense budgets are not something formal, but a means by which the management of each enterprise and the general assembly of the working people can act to obtain maximum economic efficiency, a substantial reduction of material and production expenses, a substantial increase in net output, in profits, in profitability in general—and, on this basis, resources needed both for the development fund and for the consumption fund may be created."

We can conclude that, in conformity with the new economic and financial mechanism, the income and expense budget must be conceived and prepared in such a way as to synthesize, in monetary terms, the entire economic and social activity in each unit, to reflect the manner of management of material and monetary resources, as well as the results obtained, the degree of efficiency and profitability. At the same time, it must constitute a means of analysis and control in the course of executing the plan, continually ensuring the financial stability of the economic units. From this

comes the necessity for all the worker personnel, all the departments in the unit—supply, production, technical, labor organization and so on—and not just the finance and accounting department, to work together closely, under the careful guidance of the working people's councils, on preparing, in terms of high efficiency, the income and expense budgets and to systematically, strictly supervise the way in which they are fulfilled, quickly taking or proposing the steps that are necessary.

Realities and Exigencies

According to law, the income and expense budget is prepared in close connection with the indicators of the financial plan and includes, at the level of the enterprises, the incomes, expenses and results from their activity, the receipts from foreign trade activity, the bank loans, the payments to the state budget, other incomes, resources and expenses.

From a series of actions of analysis, assistance and control performed by the financial and banking bodies in 1980 it resulted that the majority of the enterprises prepared the income and expense budget on the basis of thorough analyses, thus managing to utilize a number of possibilities and reserves for fulfilling the plan targets. So, for example, at the Iasi Wood Processing Enterprise, the preparation and finalization of the 1980 income and expense budget were done by starting from a careful examination of the structure of production. The technical, economic and financial personnel in the enterprise, with the help of those in the tutelary industrial central, established possibilities of producing assortments with high efficiency instead of others with lower efficiency. An increase of 23.6 million lei in exportation on free exchanges, a reduction of 508 cubic meters in lumber consumption and an increase of 5.3 million lei in profits were secured just by replacing the manufacture of 175,000 curved chairs with 175,000 folding chairs. In addition, at the Iasi Metallurgical Enterprise, the close collaboration between the financial bodies and those that are responsible for production, together with the workers and technicians in the sections, made it possible to establish measures for reducing metal consumption by 3 kg per ton of products, this being reflected in an increase of 10.5 million lei in profits. The list of such examples could go on.

Unfortunately, in a number of cases, full attention was not devoted to identifying all sources of income, and the amount of it was not sensibly determined. Thus, from an inspection made recently at nearly 300 enterprises it resulted that at 40 of them all sources of income were not included: 146.2 million lei in income were not taken into calculation because of omissions, and another 242.6 million lei in income were underestimated. For instance, at the Alexandria Enterprise for Electric Panels and Boards, an income of 29 million lei from production was not taken into calculation and an income of 405,000 lei from nonindustrial services and communal and housing administration was omitted. At the Craiova "Electroputere" Enterprise, the incomes in the budget were dimensioned by taking into account just the commodity-output plan, which was nonetheless 88.5 million lei below the physical-output plan. Such states of affairs indicate the necessity of acting steadily in all enterprises to know and utilize all the existing reserves for growth in income, to generally mobilize the possibilities of growth in profits.

Shortcomings are also noted with regard to the manner of formation of the enterprises' own funds. And this either due to not knowing to a sufficient extent the legal provisions in the financial field or purely and simply due to errors or

omissions. So, for example, at the Risnov Tool Enterprise, sums from reclamation and from the dismantling of fixed assets were not included in the volume of the sources needed for the economic development fund. The Tirgoviste Lathe Enterprise provided 11.6 million lei from profits for the repayment of bank loans, although there were no installments falling due in 1980, and the Iasi Knitted Cloth Enterprise established for such a purpose sums too high by 33.3 million lei.

A special problem that is posed along with the adoption of the income and expense budget by the general assembly of the working people in each enterprise is that of the way in which its provisions are divided up according to shops, sections and factories. The importance of this operation is determined by the fact that worker self-management and economic and financial self-administration must be accomplished practically with the participation of all the working people in a socialist unit, through their conscious action for fulfilling the plan targets for physical output, for fulfilling and overfulfilling the value of the net output, the profit and profitability and, hence, the income and expense budget.

Practice has shown that the better the systematic, day-by-day supervision of the manner of fulfillment of the plan indicators and the provisions of the income and expense budgets is organized, the more precisely it is possible to know and pinpoint possible lags or excesses in consumption or expenses, which creates possibilities of intervention by taking prompt corrective steps whenever necessary. So, for example, at the mining units of the Baia Mare Central for Nonferrous Ore and Metallurgy, including also the Sasar mining operation, the fulfillment of the quantitative targets for extracted ore are followed daily, starting from the work formation, shift, mine, sector and the operation as a whole. In order to quickly know the quantities of metal contained in the extracted ore the system of provisional 10-day checks was instituted, an action that facilitated the taking of the corrective steps in advance, such as reassignments of personnel and equipment, thus providing for the month-by-month fulfillment of the plan for all physical assortments of metal and of over 80 percent of the growth in income by improving the quality of the extracted ore. At the Fagaras Chemical Combine, the management analyses daily the production indicators, establishing concrete measures for eliminating the possible technical defects in installations and for regularizing the deliveries. At the same time, the stage of the receipts and the evolution of the stock of finished products are followed. Monthly, the management of the combine, of the sections and departments, together with the secretaries of the party organizations and the trade-union organizers, analyses the fulfillment of the provisions of the income and expense budgets, starting from the situation of the fulfillment of the efficiency indicators.

However, there are also enterprises that do not concern themselves as they should with organizing as quick and efficient an internal information system as possible, which prevents systematic supervision and knowledge of the way in which the economic activity is unfolding and the plan indicators are being fulfilled. Such is the case of the Baia Mare Machine Enterprise for Mining Machinery and Equipment, which confines itself just to simple "signals" that the finance and accounting department puts at the disposal of the other specialized departments, depriving the unit's management of the possibility of knowing the realities in depth and of exercising its decision-making authority as it should. The consequence was that this enterprise found itself in a difficult financial situation, concretized in a lack of solvency, loans not paid back on time and other such negative phenomena. Taking into account some situations of this sort, we believe that it would not be inconsequential, in

each economic unit, to subject to a critical analysis the way in which the fulfillment of the physical and value plan indicators, that is, of the income and expense budget, is organized and carried out, so as to find everywhere a suitable system for closely following--at as short intervals of time as possible and on all levels of the enterprise, from each workplace to its management--the course of the technical, economic and financial activity. Only in this way will it be possible to pinpoint the deficiencies and establish immediate measures for eliminating them, in order to completely fulfill the plan and the budget.

In judging the importance and necessity of exemplarily fulfilling the income and expense budget, it is necessary to start from the fact that each socialist unit can must always contribute more to the growth of national income, a stable foundation for the economic and social progress of socialist Romania. A few data on a macroeconomic scale are quite conclusive. Thus, a reduction of just a single percent in the percentage of material expenses in the national product is equivalent, at the level of 1980, to about 14 billion lei in additional national income. Likewise, an increase of just 1 percent in labor productivity in industry is equivalent to a production increase of over 7 billion lei.

Preparation and Substantiation of the 1981 Budget

The preparation, discussion and adoption of the 1981 income and expense budget in each socialist unit are of special importance, in view of the necessity of a good start in the next five-year period, in fulfilling the tasks and objectives established by the 12th Congress of the Romanian Communist Party. As Comrade Nicolae Ceausescu pointed out at the plenum of the RCP Central Committee on 14-15 October of this year, "Decisive measures for increasing the economic efficiency and continually reducing the material consumptions, which, unfortunately, continue to still be quite high, are necessary. This is the only real way to increase national income, to increase national wealth and raise the general profitability of economic activity, to provide the resources needed for developing society, for increasing the material and spiritual well-being of the people."

From this come a number of special exigencies that must be taken into account in preparing and substantiating the income and expense budget for next year. We want to refer below to some of these exigencies.

First, steady action must be taken to completely contract for the sale of the commodity output in 1981 on the domestic market and through exportation and to achieve the technical-material supply, along with concretizing the programs for cooperation in production among the various enterprises, on the basis of complete itemization, according to assortments of physical output. In dimensioning the income from foreign trade activity, for example, it is necessary to have in view the providing of the commodity supply earmarked for exportation, a field in which the targets must be considered minimums, the raising of the percentage of assortments that highly utilize raw materials and manpower, in order to obtain better foreign prices. Such measures are indispensable for achieving the planned equilibrium of the balances of trade and payments.

Second, the entering of each expense in the budget must be done after a rigorous critical analysis, which would permit the elimination, postponement or reduction of everything that is not justified or is not absolutely necessary and expedient, with

a strict policy of economy being observed. A special accent must be put on reducing all administrative, management and maintenance expenses and, in general, any expense with an unproductive character. From this viewpoint, the 1981 income and expense budget must reflect strikingly the concern and responsibility of each staff of working people for doing everything to economise on material and financial resources, for not allowing the wasting of any gram of resource or the unjustified spending of any leu, regardless of from what funds or for what purposes. It is necessary for the dominant trend to be the reduction of any expense, the elimination of imports, the economization of raw materials and energy, the recovery and reuse of materials, subassemblies, spare parts and other available resources.

Finally, the income and expense budget for next year must be based on a series of special programs, above all on the programs for growth in labor productivity and reduction of material production expenses, firmly setting any activity on the economic principles of high efficiency.

In fulfilling these tasks, a special role and a great responsibility devolve, of course, upon the financial personnel in the enterprises, centrals and ministries, called upon to act with all possible determination to prepare and execute the income and expense budget as well as possible, to apply the new economic financial mechanism with greater efficiency in all fields of social life in our country.

INCREASED SAVINGS VIEWED AS REFLECTION OF INCOME GROWTH

Bucharest REVISTA ECONOMICA in Romanian No 44, 31 Oct 80 p 13

/Article by Prof Dr Mircea Popovici, chairman of the Administration Council of the Savings and Loan Bank/

/Text/ The year 1980 marks the conclusion of the current five-year plan with notable progress in Romania's socioeconomic development as well as the beginning of a new five-year plan wherein we shall enter upon a new stage of construction of the fully developed socialist society and Romania's advance toward communism, which stage will place us on a par with the medium developed countries.

The results obtained in fulfilling the plan of socioeconomic development for 1976-1980 provided for intensive development of the productive forces and sustained growth of the national wealth and led to radical changes in society as a whole and continued improvement in the entire people's material and cultural living standard. Net wages are up 30 percent in the current five-year plan compared with the planned 20 percent increase, and the public's total incomes have increased from 247 billion lei in 1975 to 363 billion lei in 1980, not including the 40 percent gain in the public's incomes out of the social consumption fund.

All these major gains in workers' incomes have resulted in a steady increase in savings at the CEC /Savings and Loan Bank/, a banking institution authorized to organize reception and maintenance of the public's savings deposits.

Compared with other economic indicators affecting the public's savings, deposits in the CEC and the balance of credits it granted for the 1976-1979 period increased annually (See table).

The progress made in enhancing the public's material and cultural welfare has created a permanent basis for greater savings opportunities and faster growth of the total amount deposited by the public in the CEC and of the volume of credits granted the public to build and purchase privately owned housing, as indicated by the economic indicators presented below.

At the close of this year the total amount deposited by the public in the CEC will be 2.2 times greater than that at the end of 1975 and about 12 times greater than it was 15 years ago at the end of 1965. The average annual growth rate of the sum total in 1965-1980 was very high, amounting to 17.8 percent.

	1976	1977	1978	1979	1979/1976
1 Venitul național	114,5	107,8	107,5	107,7	125,6
2 Veniturile bănești ale populației	109,8	108,5	112,0	109,7	128,5
3 Desfacerile cu amănuntul prin comerț socialist	108,8	106,8	111,9	107,1	128,6
4 Soldul general al depunerilor populației la C.E.C.	116,0	118,1	125,2	112,2	165,9
5 Soldul creditelor acordate populației pentru construirea și cumpărarea de locuințe	114,0	108,2	114,5	108,7	136,0

1. National income
2. Public's cash incomes
3. Retail sales through socialist trade
4. Public's total deposits in the CEC
5. Total credits granted the public to build and purchase housing

The high level of the public's savings in the CEC has also been maintained in the last part of the current five-year plan: As of 1 September 1980 the total public's savings was up 20.7 percent from the start of 1979.

The Romanian workers' ability to save in order to meet future needs (especially to buy expensive and more durable commodities) is also reflected by the proportion of the total savings in the public's total available cash resources, which now amounts to 72.7 percent.

Expansion of the savings effort was also encouraged by making an increasing volume of expensive commodities available to the public through socialist trade that are usually purchased out of savings accumulated over a certain period of time. Savings not only limit consumption but also expand and diversify it, so that the process of saving is constantly expanding and spreading among the public. While at the beginning of 1976 Romania's population was holding 11.3 million savings passbooks and private accounts in the CEC, as of 1 September 1980 they numbered 17.5 million, or 6.2 million more than at the start of the five-year plan and averaging one active passbook to 1.3 inhabitants. Note also that there has been a great increase in the number of depositors in villages, where the number of passbooks has reached 4.4 million compared with 3.2 million at the start of the five-year plan and averaging one passbook per 2.5 inhabitants.

Savings organized by the CEC have also been encouraged by the benefits and advantages accorded depositors, especially use of the deposits to obtain major sums in the form of interest and prizes granted by the CEC, which have amounted to about 20 billion lei in the last 10 years. As of 1 September 1980 the public was holding over 4.3 million savings passbooks with interest and prizes of passenger cars, which won 5,877 prizes of passenger cars in 1979 in quarterly lotteries and 3,207 passenger cars in the first half of 1980, to the total value of more than 635 million lei.

Alongside the effort to attract the public's cash savings and other activities, the CEC is carrying out the party's and state's policy of aiding citizens with credits who wish to build their privately owned dwellings or to purchase out of the state fund dwellings that they occupy as tenants.

To this end the CEC took over from the Investments Bank the function of crediting the public for construction or purchase of privately owned dwellings as of 1 January

1970. Since then 923,263 loans have been granted out of the funds of the CEC to build or purchase privately owned dwellings to the value of 39,799,700,000 lei, the balance of the credits granted being 27,529,700,000 lei as of 30 September 1980.

The sums deposited in the CEC are returned to economic circulation either by way of state financing or crediting of socioeconomic capacities or by way of the CEC's crediting of the public, the savings forming the organized framework wherein the public's individual interests are harmoniously combined with those of society, namely the financial requirements for expanded socialist reproduction. This gives rise to one of the distinctive features of the process of organized saving, namely its twofold character as a process of temporary redistribution on the microeconomic level and one of permanent redistribution on the macroeconomic level.

The prospects of growth of the public's incomes and especially of workers' wages are particularly important to future development of the savings effort. In accordance with the Directive-Program for Raising the Living Standard, the public's total real incomes will be up 23-25 percent from 1980 in 1985, and the average real wage will be increased by 16-18 percent. The minimum wage will be raised from 1,425 lei a month in 1980 to 1,630 lei in 1985, in addition to the allowance for children and the other incomes coming out of the social consumption funds. Peasants' real incomes will be up 20-25 percent and nominal state social insurance pensions will be increased by an average of 23 percent.

The role of the savings effort grows steadily under these circumstances. The CEC is expected to contribute increasingly to consolidation of Romania's monetary system and of the purchasing power of the national currency and to implementation of the party's and state's policy on finance and credit.

DATA ON INCREASED PENSION COSTS, NUMBER OF PENSIONERS

Zagreb DELEGATSKI VJESNIK (supplement to VJESNIK) in Serbo-Croatian
29 Oct 80 pp 21-22

[Text] The Federal Executive Council has submitted to the SFRY Assembly the Report on Administration of the Old-Age and Disability Insurance System in 1979. Since this is an area which has an important place in the system of personal and community expenditure. The report is to be used by the delegates in their quite comprehensive examination of this problem area and in proposing solutions in the new pension system which is now being prepared. At the same time it will contribute to the undertaking of steps and efforts to implement the policy of economic stabilization in this area.

Self-Management in Old-Age Insurance

The report states that constitutional organization of self-managed special-interest communities for old-age and disability insurance has by and large been performed successfully, but it is not regarded as completed, but is viewed as an ongoing process. Particular attention is paid to creation of conditions for teamwork and group decisionmaking in accordance with the initiative of President Tito. Changes have already been made in the term of office of the chairman of the collective body in Bosnia-Hercegovina and Croatia.

The workers and their delegations and delegates have been afforded more direct influence in the preparation and adoption of self-management acts. In the field of planning development, however, satisfactory results have not been achieved. Only in certain communities has it been provided that self-management accords be concluded on funds for old-age and disability insurance. There are also shortcomings in the procedure for internal self-management organizations. Though the interests of the workers and pensioners are represented more and more within the communities, the scope of the rights, obligations and responsibilities of the communities is narrow, and their material base is not adequate for fuller development of self-management relations.

Protection of Pensioners With Low Income

Vocational rehabilitation and the hiring of victims of work accidents were the subject of self-management regulation in 1979. In conformity with the Law on Associated Labor, emphasis was on strengthening the role and responsibility of organizations of associated labor in guaranteeing worker rights.

Matters related to protection of pensioners with low incomes (the lowest pension benefit, the welfare pension supplement, etc.) have also been regulated more favorably. Also, broader opportunities now exist for extended insurance coverage of spouses of personnel in diplomatic and other missions. Along these lines the possibility of purchasing qualifying lengths of service has been envisaged in Bosnia-Hercegovina, Serbia and Kosovo.

Regulation and conformity with self-management has been manifested most markedly in the domain of bringing pensions into line with economic trends. Average benefits of pension recipients have increased slightly more than personal incomes. That is, whereas the average nominal growth rate of personal incomes was 21.1 percent, the growth rate of pensions was 21.8 percent. However, the report points out that the real dimensions of the faster growth of pensions have not been ascertained. At the beginning of each calendar year pensions are raised according to data on the trend of the cost of living and personal incomes in the previous year. Then during the year they are raised on an ad hoc basis by approximately one-fourth of the rise of the cost of living in that year on the average. This tends to give the impression that the growth of pensions is more favorable than that of personal incomes.

The report also states that the process of extending old-age and disability insurance coverage to farmers has gone forward satisfactorily and that the associated farmers are treated the same as workers in associated labor. A significant step has also been taken in the old-age and disability insurance of private farmers. This has gone furthest in Croatia, where compulsory insurance against all types of perils has been established. In Macedonia and Slovenia compulsory old-age insurance has been introduced, but in the other republics and provinces preparations are being made for optional insurance of farmers.

Problems

Problems have arisen in administration of old-age and disability insurance, especially in implementing Article 63 of the present law concerning pensionable service which insureds have completed in the territories of two or more communities. That is, the provisions of that article have not been implemented up to now, since a certain number of communities have contested rulings pertaining to existing pensions and to pensionable service performed before 1973, and the mutual agreement of the republics and provinces would have to be obtained on this issue.

There also exist difficulties and delays in discharging the obligations of the Federation concerning the pensions of veterans, which is having an adverse effect on the business operation of the self-managed special-interest communities.

The Growing Number of Pensioners

The report states that in 1979 there were 1,540,683 pensioners in our country. This means that their number increased 4.9 percent over 1978. After several years of mild growth, since 1977 there has again been a faster influx of new pensioners. The highest growth rate, 7.6 percent, was recorded in Serbia proper, which was followed by Bosnia-Hercegovina and Kosovo.

These results nevertheless are in line with forecasts based on demographic surveys, which show that elderly workers with long pensionable service will comprise an ever greater proportion every year. This must be taken into account, then, in setting the age limit and other qualifying conditions for pensions.

This section of the report especially emphasizes that in 1979 and this year there has been an appreciable increase in the number of disability pensioners in certain republics and provinces. The largest growth, 12.4 percent, was recorded last year in Serbia proper, which was followed by Bosnia-Hercegovina and Macedonia. This points up the need to establish and consistently enforce uniform and objective criteria in evaluation of disability.

It is felt that the faster increase in the number of disability pensioners has in part been caused by momentary economic difficulties. Certain organizations of associated labor are trying to free themselves of workers with reduced work abilities and to exert pressure on commissions for expert evaluation of disability.

Results of Financial Operations

The revenues of self-managed special-interest communities for old-age and disability insurance amounted to 90.5 billion dinars in 1979 and were up 23.2 percent over 1978. The largest growth was recorded in Macedonia, and the lowest in Kosovo.

Expenditures increased more than 20 percent because of the rise in average nominal personal incomes and a 4-percent increase in the number of employees. However, there were no essential changes in the structure of gross revenues. The contribution from the personal income of workers is still the predominant source of revenue. The share of this source increased from 64 percent in 1978 to 64.8 percent in 1979.

It is significant that the share of contributions from income of basic organizations of associated labor dropped 1.6 percent last year. Only in Serbia proper did this contribution have a share of 46 percent in gross

revenues and represent the predominant source of revenue. The share of this income, incidentally, ranges from 1.2 percent in Macedonia to 15.6 percent in Croatia.

Old-age and disability insurance payments increased from 70 billion dinars in 1978 to 88.6 billion dinars in 1979. This 26.6-percent growth of payments is in line with the average annual growth rate of payments in the period from 1973 to 1978. It was mostly influenced by the increase in the number of pensioners, by the adjustment of pensions to economic trends and by the ad hoc adjustment during last year.

Expenditures for Special Purposes Are Also Increasing

Expenditures to pay pension benefits had a share of 77.5 percent in total expenditures. A certain decline in the share of these expenditures from the previous year indicated an increase in the share for various types of contributions for special purposes and for the expenses of the service. The largest item recorded was expenditures for health care of pensioners, representing 9.7 percent of total expenditures, or 8.6 billion dinars.

In this connection the issue was raised of whether it is justified to provide funds for health care and similar needs of pensioners through the self-managed special-interest communities, which then distribute them. It is felt that the community's role as a middleman does not conform to the principle of free exchange of labor, nor to the character of the community.

The reserve funds of the community decreased from 9.8 billion dinars in 1978 to 6.8 billion dinars in 1979. The predominant share of this was held in communities in Croatia and Serbia. Reserves are being exhausted because revenues are growing more slowly than expenditures. This is having an adverse effect on the possibility of balancing revenues and expenditures and is hampering financial operation.

DATA ON 1980 GRAIN, OTHER CROPS IN CROATIA

Zagreb DELEGATSKI VJESNIK (supplement to VJESNIK) in Serbo-Croatian
29 Oct 80 p 18

[Text] Final figures on the harvest of early crops and early fruits for 1980 have been collected and collated in the republic bureau of statistics. Along with a comparison of data on production this year with last year and with the average over the last 10 years for the most important early crops, we give separately the production results for wheat, which unquestionably is our most important grain.

Comparative Figures

This year's harvest of all early grains is larger than the 1979 harvest largely because the yield per hectare is considerably higher than in 1979, particularly for rye, barley and oats.

The area planted to wheat was 2 percent greater and that planted to barley about 10 percent greater than last year. The areas planted to oats and rye have been dropping steadily for quite a few years now.

By contrast with grain, rapeseed production dropped considerably--only about 70 percent of the 1979 area was planted, that is, the area planted was 7,460 hectares smaller than last year. The yield per hectare was also down 6.5 percent, or 1.6 quintals per hectare, from last year, which had an additional adverse effect on the total harvest of this industrial crop.

Figures comparing 1980 with the 10-year average (1969-1978) show that less area was planted to wheat, rye and oats, the area planted to barley was 6.3 percent greater, and the area planted to rape was up 105.6 percent. The percentage by which the area planted to rape increased appears very impressive. Yet had the area planned actually been planted to this crop in 1980, that percentage would have been considerably higher--190 percent.

More detailed figures on all this are given in Tables 1-3.

Table 1. Production of the Most Important Early Crops

	Harvest, in cars			Indices	
	ø 1969-1978	1979	1980	1980/1979	ø 1980/1969-1978
Wheat	111,169	103,918	112,008	107.8	100.7
Rye	1,774	1,064	1,147	107.8	64.7
Barley	10,847	12,168	15,176	124.7	139.9
Oats	5,940	5,577	6,079	109.0	102.3
Rape	1,736	6,123	4,018	65.6	231.4

Table 2. Area Harvested

	Area Harvested, in hectares			Indices	
	ø 1969-1978	1979	1980	1980/1979	ø 1980/1969-1978
Wheat	373,155	335,263	342,015	102.0	91.7
Rye	11,776	6,808	6,216	91.3	52.8
Barley	57,038	55,262	60,605	109.7	106.3
Oats	39,368	35,837	33,409	93.2	84.9
Rape	8,445	24,823	17,363	69.9	205.6

Table 3. Average Yield Per Hectare

	Yield, in quintals per hectare			Indices	
	ø 1969-1978	1979	1980	1980/1979	ø 1980/1969-1978
Wheat	29.8	31.0	32.8	105.8	110.1
Rye	15.0	15.6	18.5	118.6	123.3
Barley	19.0	22.0	25.0	113.6	131.6
Oats	15.1	15.6	18.2	116.7	120.5
Rape	20.5	24.7	23.1	93.5	112.7

Wheat

Because of the great importance of the wheat harvest, Table 4 gives a more detailed survey of the results achieved in 1980 by communities of opstinas, with the socialized sector given separately from the private sector.

This year's wheat harvest was up 7.8 percent over 1979 and 0.7 percent over the 1969-1978 period. Here we should mention that this largest harvest is the result of the higher yield per unit area achieved almost exclusively on the land of private farms. In the socialized sector the yield of 46.3 quintals per hectare, that is, is at the level of the average over that 10-year period. However, when we realize that this year's wheat production had to deal with various difficulties virtually from planting to harvest, this production can confidently be called satisfactory.

Table 4. Area Harvested, Average Yield and Total Production of Wheat

1980/1969-1978 average	87.7	114.6	98.8

ZO = Community of Opstinas; GZO = Community of City Opstinas.

Along with the unfavorable weather conditions during the growing season, there was also a shortage of manufactured fertilizers at planting time and later when the wheat should have been dressed. All of this had to have an effect on average yields per hectare and on the total harvest.

Harvesting took an unusually long time because of the frequent rains. The difficult harvesting conditions caused several breakdowns on combines, and there were not always enough spare parts, especially for Yugoslav-made combines. Because of the high moisture content of the grain almost the entire harvest from the socialized sector had to go through driers.

The difference between the socialized and private sectors, amounting to about 20 quintals of wheat per hectare, shows that there still exists a considerable potential for increasing production on the land of private farmers.

Early Fruit

It can be said of this year's harvest of sweet and sour cherries (Table 5) that it was smaller than last year's and smaller than the 10-year average.

Table 5. Harvest of Early Fruit

	Harvest, in cars			Indices	
	∅ 1969-1978	1979	1980	1980/1979	∅ 1980/1969-1978
Sweet cherries	747	829	683	82.4	91.4
Sour cherries	1,074	1,151	915	79.5	85.2
Apricots	163	127	142	111.8	87.1

The apricot harvest was somewhat better. In general the production of these fruits has not undergone significant changes over the last 10 years. The years 1971 and 1974, which were unusually abundant years, made an exception (Table 5).

BRIEFS

JAPANESE LICENSED X-RAY FILM--By the middle of next year the "Alkaloid" Chemical, Pharmaceutical and Cosmetic Industry [in Macedonia] will begin to produce x-ray film, which to date can be acquired only through import. The production will be carried out according to a license from the Japanese company "Fujifilm." It is planned that the first phase will include putting the x-ray film into rolls and final packaging, and the second phase will introduce the spreading of the light sensitive halogen emulsion on the polyester support. The capacity of the plant will be one million square meters of film annually, in one shift. According to the agreement between the two companies, all the equipment is due to arrive from Japan between 6 December and the end of the month. The specialists who will manage this operation are already in Japan for 3 months of specialization at one of "Fujifilm's" plants. They include 12 engineer-technicians and 6 trained workers. In March of next year these people, along with specialists from Japan, will begin the installation of the machinery (both imported and domestically produced) and will carry out tests of the technical production and technological capabilities of the machines. By the middle of the year the operation will be in test production and by June it will be operating as an organizational unit of the "Gotovi lekovi" OOZT [Basic Organization of Associated Work] of "Alkaloid" and will begin regular production. The site for the x-ray film plant has been prepared and is located in the western industrial zone where the facilities of the "Khemikalii" and "Dijazofotomaterijali" OOZT's are also located. (B.M.) [Text] [Skopje NOVA MAKEDONIJA in Macedonian 22 Nov 80 p 5]

MACEDONIAN TELEPHONE SERVICE--By the end of 1985, it is anticipated that there will be 254,000 telephones in Macedonia. This number will increase the ratio of telephones from the current 8.1 per 100 inhabitants to 12.33 per 100. However, this is poor in comparison with the Yugoslav average, which is planned to be 17.77 per 100 inhabitants by the end of the same period. The accelerated development of this branch will enable every other household in the urban areas to have a telephone. The president of the PTT told the delegates to the assembly of the League of Communists of Macedonia that the major portion of the Republic Fund will be used for building of the PTT network in the undeveloped and hilly and mountainous areas. The total number of telephones [in these areas] will increase from the current 4,500 to more than 30,000. In the undeveloped areas there are now 0.4 telephones per 100 inhabitants, and by the end of the coming medium-term plan it is anticipated there will be 3.5. There will also be telephones in the villages, but it will be necessary to ensure individual participation of 5,000 dinars in order to obtain a telephone. FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

SCHEDULE OF INTERNATIONAL FLIGHTS FOR NOVEMBER-MARCH PERIOD

Tirana BASHKIMI in Albanian 1 Nov 80 p 4

[Announcement from Albtransport]

[Text] From 1 November 1980 to 31 March 1981, the schedule for airplanes of international airlines will be as follows:

1. Interflug—(IF-390/391)--civil air transport enterprise of the GDR will fly on Monday, once every 2 weeks, on the Berlin-Budapest-Tirana route and return arriving at Rinas airport at 1000 hours and departing from Rinas at 1110 hours.

2. JAT-(JU-480/481)--Yugoslav air transport enterprise, will fly on Monday, every week, on the Belgrade-Tirana route and return, arriving at Rinas airport at 1410 hours and departing from Rinas at 1510 hours.

3. Olympic-(OA-115/116)--national air company of Greece, will fly on Tuesday, every week, on the Athens-Ioannina-Tirana route and return, arriving at Rinas airport at 1210 hours and departing from Rinas at 1310 hours.

4. TAROM-(RO-251/252)--civil air transport enterprise of the Socialist Republic of Romania, will fly on Wednesday, every week, on the Bucharest-Tirana-Rome route and return, arriving in Rinas airport from Bucharest at 0900 hours and leaving for Rome at 0950 hours; it will return to Rinas from Rome at 1400 hours and will depart from Rinas for Bucharest at 1500 hours.

5. MALEV-(MA-430/431)--civil air transport enterprise of the Hungarian People's Republic, will fly on Thursday, every week, on the Budapest-Belgrade-Tirana route and return, arriving at Rinas airport at 1110 hours and departing from Rinas at 1210 hours.

Note: Passengers must be at Rinas airport 1-1/2 hours before the departure of the airplane, otherwise Albtransport is not responsible if they miss the flight.

Tirana, 29 October 1980.

POOR PLANNING, DESIGN OF BUILDINGS CRITICIZED

Tirana BASHKIMI in Albanian 5 Nov 80 pp 1, 2

[Article by Sokrat Mosko, director of the Institute for City Planning Studies and Designs and Architecture]

[Excerpts] Successes in city planning studies and design do not conceal the shortcomings and deficiencies for which we have attempted to find the causes and to determine the measures which must be taken to improve the situation. Such defects have appeared in the design for the Tepelene hospital and the Shkoder railroad station, cases in which the buildings were not organically related to the real conditions of the climate and the terrain. This deficiency is a result of failure to achieve the necessary depth in scientific work, insufficient effort to learn the situation in detail, to know factors such as the climate conditions of the zone and the microclimate of the construction site, the material base and the mechanization capacities and abilities of the enterprise constructing the work, the results of similar projects executed by the enterprise and many other factors whose scientific analysis would have resulted in a high level solution.

Deficiencies also appeared in the coordination of the design work among the various elements, in the erroneous practices of fragmented work, when the project is not considered in all its aspects but it begins with the architect and the construction or installation activities become mechanical processes, which results in serious consequences. This has happened in the case of some housing units in Vlore, in the railroad station in Mjede, etc. Such situations have also occurred in city planning studies, such as the study of the hill in Sarande, which was executed without the necessary knowledge of the situation of the city, its climate conditions, the microclimate of the hill and its connection with the city.

In general, efforts have been made and are being made in city planning to abandon completely the erroneous practice of many years past where the city plan is thought to be and is drawn up as simply a system of roads where a few buildings are placed. This has been inadequate. Therefore, more attention should be concentrated in this area so that the city plan will be preceded by accurate scientific work, for the study of the situation, for comparison with the past, discovering what life, development, the future and many other topogeological,

climate, and traditional factors dictate, thus arriving at a solution for the harmonious development of the city or of the residential center.

In architectural designs the shortcomings which are obvious and which have resulted in negative consequences are, in particular, the failure to examine analytically the design task and the lack of comprehensive studies on what has been done so far and what must be done.

In regard to design tasks, we must say that, in general, they are on a low level. The investors do not demonstrate sufficient concern; they allow them to be prepared by individuals who do not use scientific criteria.

CSO: 2100

VIOLATION OF TECHNOLOGICAL, LABOR DISCIPLINE CAUSES LOSSES IN AGRICULTURE

Sofia KOOPERATIVNO SELO in Bulgarian 5 Nov 80 pp 1, 2

[Article by Marko Markov, chairman of the Control Council of the National Agroindustrial Union: "Discipline and Responsibility--Everywhere and From Everybody"]

[Text] The labor collectives in the National Agroindustrial Union launched a nationwide socialist competition this year and greeted the 36th anniversary of the Ninth of September revolution in our country with new successes and fulfillment of the 1980 plan and the Seventh Five-Year Plan.

As a result of the introduction of the economic approach and the new economic mechanism, most of the units of the National Agroindustrial Union during the first nine months of 1980 successfully fulfilled their counterplans in respect of a number of indicators. But the results would have been better still if throughout the National Agroindustrial Union there had been strict observance of technological, labor, contractual and financial discipline and if speedy and effective measures had been taken by the managements of its units to prevent certain violations.

By the decision of the Executive Committee of the Central Council of the National Agroindustrial Union and measures taken on 18 August the managements of economic organizations and units within the National Agroindustrial Union were charged within the period prior to 15 September 1980 to look into the state of technological, labor, contractual and financial discipline and take concrete measures for strict observance thereof. A recommendation was also given to the Control Council of the National Agroindustrial Union to make independent checks in economic organizations and units on the measures taken and to inform the Executive Committee of the results.

The Control Council checked the state of technological, labor, contractual and financial discipline in the OAPS [okrug agroindustrial unions] at Burgas, Vidin, Veliko Turnovo, Varna, Stara Zagora and Turgovishte, the Bulgarian Tobacco TPO [Trade and Industrial Trust], the Bulgarian Sugar Industrial-Agrarian Trust, the Bulgarian Fruit State Economic Trust, the Wine

Industry State Economic Trust, the Dairy Industry State Economic Trust, the Rhodope State Economic Trust, the Cattle and Sheep-raising NPO [Scientific Production Trust] and the Poultry-farming NPO and analysed certain data of the accounting, statistical and operational reports for the National Agroindustrial Union system.

The checks and analysis of discipline in all its different forms show that the violations of technological discipline boil down mainly to nonperformance of certain important agrotechnical and zootechnical measures for the raising of crops and livestock as envisaged in current technological and engineering plans. Thus, for example, the corn for grain, soybeans, sunflowers and other crops were not earthed up for the first and second time on all croplands or at the specified time. The requirements set for the quality of soil tillage were lessened. Irrigated croplands were not used efficiently. Timely and high-standard plant protection and weed control were not carried out.

Engineering projects for corn for grain and for certain other basic crops were not backed up with the necessary fertilizers, herbicides, high-efficiency machinery, spare parts etc.

This (in addition to adverse climatic conditions) contributed to the non-achievement of the targeted 1980 yields and output of corn for grain, sunflowers, soybeans, sugar beets, common beans and other crops.

Now when the foundations for next year's grain production are being laid, in some okrugs (Turgovishte, Mikhaylovgrad, Lovets etc.) there have been occurrences of planting with substandard and inadequately treated seeds, inadequate fertilization and other violations of the technology for the raising of wheat, barley and other fall crops.

There are also violations of pork production technology, for which reason a lower average daily gain was obtained, the finishing period was lengthened, and overconsumption of concentrated feed and high swine mortality were permitted.

Due to violations of technological discipline during the first eight months of 1980 substandard output was produced, and some of it rejected, at the Rhodope State Economic Trust, the Poultry-farming NPO, the Bulgarian Fruit State Economic Trust, the Fishing Resources State Economic Trust etc.

Technological control is also inadequate at the Wine Production State Economic Trust in the preparation of output for export, for which reason claims have been filed over tons of wine for Japan and Poland.

Many problems still remain unsolved in respect of the quality, bagging, packaging and artistic design of some products of the food, wine and tobacco industries.

The nonobservance of labor discipline is alarming. The checkup and analysis established that the participation of workers in agricultural activities is erratic. In the second quarter of 1980 alone, 43,102 fewer workers than planned were working and 11,910,817 fewer man-days than planned were worked. The average monthly time worked by workers permanently participating in production was 10-15 man-days at some agroindustrial complexes instead of the 25 man-days targeted in the plan. Optimal use was not made of working time in plant-growing due to late arrival at work and early leaving of the sites.

The labor of office and manual worker brigades is not utilized with adequate efficiency. Thus, at the Turgovishte agroindustrial complex 494 office and manual workers from different enterprises and departments picked 9104 kilograms of berries as against the norm of 24,300 kilograms; another 399 office and manual workers picked 29,860 kilograms of red tomatoes as against the norm of 109,850 kilograms. At the Ugurchin agroindustrial complex brigade members worked 20,062 man-days, fulfilling 10,318 labor norms (54 percent fulfillment), while at the agroindustrial complex in the village of Dermantsi brigade members worked 4575 man-days, fulfilling 1923 labor norms (42 percent fulfillment). Similar cases were found in other agroindustrial complexes and okrugs. In other words, the time worked hardly covered transportation costs for the brigade members.

Analysis showed that in the food, wine and tobacco industries during the same period 117,051 man-days were not worked due to absences approved by management and due to absences without leave, while 238,000 man-days (reduced to 8-hour working days) of overtime and 109,000 man-days of idle time and unnormed work due to lack of raw materials were worked and paid for. Thus at the Bulgarian Tobacco TPO 25,918 man-days were not worked, but 47,545 man-days of overtime were paid for; at the Rhodope State Economic Trust 17,469 man-days were not worked, but 24,445 man-days of overtime were paid for; at the Bulgarian Fruit State Economic Trust the figures are respectively 17,575 and 20,812 man-days, at the Dairy Industry State Economic Trust 6341 and 29,630 man-days respectively, etc.

A number of violations of contractual discipline were found, too. Contracts are still not being made at the same time that counterplans and engineering projects are worked out. Contracts are made very late and for amounts less than the authorized control figures, as was the case with tomatoes and grapes in Pleven and Sliven okrugs in 1980, ready-to-serve frozen foods in the unit of the Bulgarian Fruit State Economic Trust in Ruse etc., while the plan for the sale of 35 million liters of beer of the Bulgarian Beer State Economic Trust in 1980 was not covered by contracts despite the serious warnings given during the year by the leadership of the National Agroindustrial Union.

Contracting under the 1981 plan lags behind, too. Out of the envisaged 17,465 contracts involving 6,337,049,000 leva, by 31 August 1980 only 4864 contracts involving 1,645,571,000 leva had been entered into. The measures that have been taken in this matter do not suffice.

Contracts are still not being used as an economic lever in the activity of economic organizations and their units. The practice of "forgiveness" in the event of nonperformance has not been halted. In this regard there are violations by even some bodies such as the Okrug Agroindustrial Union in Yambol (it made the unlawful decision to exculpate the livestock purveyors who failed to perform their contractual obligations this year), the Okrug Agroindustrial Union in Pleven (it instructed a unit of the Dairy Industry State Economic Trust not to pay penalties for the nonperformance of a contract by farms to supply raw milk), the ONS [okrug people's council] in Sliven (it instructed a unit of the Dairy Industry State Economic Trust to hold back on the payment of penalties by a trade organization for unperformed contractual obligations to sell finished output) etc.

The managements of agroindustrial complexes do not seek a penalty from other economic organizations inside and out of the National Agroindustrial Union for nonperformance of contractual obligations plus damages, for nonfulfillment of plan etc. The agroindustrial complexes in Mikhaylovgrad Okrug during the first half collected only 7000 leva in penalties but paid out 584,000 leva; the agroindustrial complexes in Razgrad Okrug collected 15,000 leva but paid out 180,000 leva; the agroindustrial complexes in Vratsa Okrug collected 7000 leva but paid out 322,000 leva etc.

Despite the measures taken by governing body of the National Agroindustrial Union, of the economic organizations and units, of the control agencies of the National Agroindustrial Union control system and agencies of the Ministry of Finance there are still serious violations of financial discipline.

Normative working capital as of 30 September was overstated due mainly to unfinished production. For unsold assets in the form of physical commodities as of 15 September agroindustrial complexes in Vidin, Burgas, Turgovishte, Vratsa and other okrugs were in default and were unwarrantably paying interest and fines. Working capital was 4,369,000 leva in excess of the normative. Overdue loans increased by 55,522,000 leva, the total amount thereof being 135,244,000 leva. As of 30 September 1980, working capital in the amount of 16,468,000 leva had been diverted into investment, including 12,990,000 leva for agroindustrial complexes, which it will be hard to pay back at the end of the year and which will be a burden on the resources for the formation of a results-based Wage Fund.

During the nine-month period of 1980, 86,771,000 leva less than the targeted installments for farmed land, and 38,905,000 leva less than the targeted installments from the revenue of agricultural organizations was paid in, which is an obstacle to meeting the expenditures they envisaged within the National Agroindustrial Union.

Out of the 638 financial audits conducted during the first nine months, culpably caused losses amounting to 61,049,000 leva were discovered; at 449 agricultural facilities culpably caused losses amounting to

44,151,000 leva were discovered; at 131 industrial facilities, 33,383,000 leva; at 14 commercial facilities, 982,000 leva; and at 15 construction projects, 2,354,000 leva. The losses were greatest in the agroindustrial complexes--33,315,000 leva (the Dairy Industry State Economic Trust, 3,927,000 leva; the Rhodope State Economic Trust, 3,770,000 leva; the Agrokomplekt [Agricultural Equipment] ISI [Engineering Construction Institute], 1,850,000 leva etc.). The losses were due mainly to overexpenditure of materials, fuel, energy, seed and feed, to partially and completely spoiled output, illegally paid remuneration for labor and bonuses, penalties, interest and other property sanctions for unfulfilled contracts and overdue loans, above-normative working capital and diversion of the same, and direct encroachments upon socialist property.

From the analysis of the report data on plan fulfillment by the economic organizations within the National Agroindustrial Union, alarming facts were discovered regarding the first nine months of 1980 and the implementation of internal profit and loss accounting.

A number of managements of the economic organizations still are not observing the instructions of the Central Council of the National Agroindustrial Union regarding "The Organization of Internal Profit and Loss Accounting." In these organizations the normative production-cost Wage Fund, flow charts, norms and piecework rates have not been brought into line with the results-based Wage Fund. This group of economic organizations used up the anticipated annual Wage Fund before the end of the nine-month period. Nonfulfillment of the nine-month plan is excused in these organizations by the so-called failure of the plan to "dovetail;" manifestations of idleness and the lack of a good steward's elementary concern are tolerated; violations of discipline in all its different forms are tolerated; overexpenditures of materials, labor and funds are tolerated.

Not only planning agencies and financial and accounting personnel, but also control agencies at all levels must realize their part in the alarming financial condition of many economic organizations within the National Agroindustrial Union. They and they alone can and must take effective measures to cut short violations of and deviations from fixed standards, to properly implement internal profit and loss accounting and to ensure the necessary results-based Wage Fund.

Action to determine disciplinary liability was taken against 16,219 managers, specialists and workers for violations of technological, labor, contractual and financial discipline they committed during the first nine months of 1980; action to determine liability for property in the amount of 1,062,000 leva was taken against 18,782 officials, and action to determine criminal liability in the amount of 732,000 leva against 612 officials.

By decision of 20 October 1980 the executive committee punished the general directors of several trusts and the chairmen of okrug agroindustrial

unions who did not, within the specific time, look into the status of discipline. It again obliged all managers to take resolute measures for the sharp improvement of discipline in the units under their direction. It charged the Labor and Social Development Directorate with analyzing the results of brigade labor in helping agriculture and the food industry in 1980 and with suggesting measures for more effective use thereof in 1981. It obliged the legal section and court of arbitration to redirect their activity and to inform the Executive Committee of the Central Council of the National Agroindustrial Union every quarter about the state of contractual discipline; it obliged all governing bodies of sectors in the National Agroindustrial Union to include specific measures for the implementation of discipline in all their units during the adoption of the 1981 plan.

In conclusion, we must say that what has been achieved by managements and control agencies of economic organizations in the National Agroindustrial Union in respect of technological, labor, contractual and financial discipline and the implementation of internal profit and loss accounting is not satisfactory. It is not in keeping with fixed standards or capabilities, and the desired and possible final economic result has not been achieved. Ultimately, all the violations adversely affected fulfillment of the plan and provision of the results-based Wage Fund.

The analysis of the checkup shows that despite the measures that have been taken and the punishments that have been imposed the weaknesses and violations in the observance of technological, labor, contractual and financial discipline continue and arouse alarm. This makes it imperative that managements at all levels of administration and control take effective measures for a sharp improvement of discipline and for a worthy marking of our 12th Party Congress.

POMPOSITY, OBFUSCATION IN REPORT WRITING DERIDED

Prague HOSPODARSKE NOVINY in Czech 3 Oct 80 p 16

[Article by Josef Mervari: "Instructions for Writing and Reading Reports on Task Fulfillment"; passages enclosed in slantlines printed in boldface]

[Text] The last year of the 5-year plan is usually decisive for final evaluation of the fulfillment of tasks in various areas of research, development and economy. We must pay particular attention to the compilation of reports about the fulfillment of these tasks augmenting their value by the use of routine expressions which generally have a very specific and deeper meaning. To ease the work of the compilers and readers of these reports, we made a list of some of these expressions indicating their true and full meaning.

/The methodological side of the matter is somewhat more complicated and in the interest of clarity is not being expounded on in this text/--the author did not understand the report at all.

/First we will explain the theory of problem solving/--it contains everything that the author had opportunity to copy from a basic textbook on the eve of the report due date.

/It is generally known/--our deputy director said that.

/It is commonly valid/--it is applicable in about 20 percent of cases.

/We have achieved these results by a direct method/--that is, by doing subtraction and addition.

/From the 20 experimental castings we have selected 3 examples for further processing/--the other 17 were completely unusable.

/Newly developed equipment:/

--/Has shown to be very resistant under operational conditions/--we dropped it and only part of it broke

--/Is automated/--it has a switch

--/Is semiportable/--it has a handle

--/Is transportable/--it has two handles.

/Some of the typical results stated in the report/--contradictory results were eliminated.

/The agreement of theoretical basis with the actual results of the experiment/:

--/Is irrefutable/--nobody checked on it

--/Can be proven only through complicated procedures/--there was no applicable theoretical solution

--/Is satisfactory/--the theoretical basis had to be changed during the process.

/Detailed reports will be published later/--even the authors agree that the reports are unpublishable.

/There is a complete agreement on the usefulness of the proposed solution/--both authors agree on it.

/The proposed solution could give rise to only one objection/--e.g. the only one which the author can answer.

/Latest results prove the future potential of the process used/--it will not show any results for a long time to come.

/Indisputable usefulness arising from the application/--nobody expressed interest in its use.

/Data provided by Engr Zika and Engr Mika made a partial contribution to the solution of the problem/--Zika made the necessary investigations and wrote chapters 1 and 2, Mika made all the necessary calculations and wrote the remaining chapters 3 and 4, the author of the report assigned a report number, prepared the table of contents and the award recommendations.

EAST-WEST ECONOMIC COOPERATION IN THIRD MARKETS DISCUSSED

Budapest FIGYELO in Hungarian No 45, 5 Nov 80 pp 1-2

[Article by Istvan Garamvolgyi: "East-West Cooperation. Extending to Third Markets"]

[Text] News item: Nikex and the Danish firm Schanwater jointly won a public tender in Iraq in the beginning of July. The tender was held to build a waste water treatment plan for a city of 100,000 inhabitants. The value of the project is 45 million dollars of which the Hungarian share is 37 million.

Such news and facts occur rather infrequently in accounts describing the latest foreign market activities of Hungarian enterprises. The role of third market cooperation in East-West trade is as yet quite modest: in fact, it is not possible to estimate it precisely. For example, we know that the number of East-West cooperative projects increased during the past decade from 400 to several thousand and some of these also envisage cooperation in third markets. The European Economic Commission and UNCTAD publish regular surveys and studies dealing with the situation of East-West cooperation and third market cooperation. Reports on the latter subject deal mainly with the obstacles causing the slow expansion of this form of cooperation. In this connection, some useful work was performed recently at the third international symposium on third market cooperation held in the Hungarian capital under the auspices of the Vienna-based Donaueuropaisches Institut which has supported the cause of East-West trade for decades.

'Full' Signs

What are the reasons behind the interest and attention toward this topic shown by various international economic organizations and, let us add, individual states and governments? Third market cooperation is not a new form of international trade: capitalist firms, including the largest ones, have been regularly cooperating in third markets for decades. This is so mainly because the requirements and needs of the customer, especially in the case of large projects, does not always match the ability of the firm interested in the business to deliver; thus, they are forced to call in a subcontracting firm. Quite frequently, an attempt to share risks and, not least, financial problems associated with big-ticket deliveries are behind cooperation in third markets. Both ad hoc and long range cooperation in third markets are well-tried and

accepted methods in world trade. (Let us mention an example with a Hungarian angle: six West European firms, each quite important in its own right (Siemens, AEG, Brown Boveri, Alsthom, Schneider-Westinghouse and ACEC), formed an ad hoc association to design and produce prototypes for a silicon semiconductor electric locomotive made by the Ganz Electric Works and redesigned since then.)

In a wider sense, this interest and attention is based on the desire of socialist countries to use more widely and frequently a form of cooperation created by the objective facts and phenomena of the world economy and world trade. If they were not working toward this goal, they would be depriving themselves, knowingly or not, of possibilities of foreign market sales which lie within their engineering and technological capabilities.

The need and demand for cooperation in third markets is especially timely in East-West trade. East-West cooperation between socialist and capitalist firms developed at a rapid rate at the end of the preceding decade and the beginning of the 1970's, but it slowed down around the middle years of the 1970's. Its role in East-West trade and bilateral trade between socialist and capitalist countries is still quite low. (The percentage of cooperative projects within the non-ruble trade of Hungary is 6 percent while in ruble trade it is 28 percent.)

The 'Full' sign has been posted, symbolically speaking, in the markets of a number of advanced industrial countries during the recession. Willingness to engage in bilateral production cooperation has undoubtedly declined. Socialist countries are proposing third market cooperation not as an either/or option but as a both/and alternative. This means strengthening of third market cooperation while bilateral production cooperation is preserved and developed. The reason behind this slogan, wish or proposal, or whatever we call it, is rooted in realities. Third market cooperation (in the markets of another capitalist or developing country) may reduce the tensions arising in bilateral trade while helping trade development.

The First Attempts

Hungary is considered as one of the countries that can boast of relatively good results in one of the areas of third market cooperation: trilateral cooperation. This has been noted at the Budapest symposium of the Donaueuropaisches Institut. This evaluation is open to debate but the past cooperation of between Hungarian and capitalist enterprises in third markets is suitable for highlighting this topic in more concrete terms.

The first attempts toward cooperation in third markets have preceded production cooperation in our country. Komplex and the Ganz Electric Works cooperated with the Austrian firm of Simmering-Graz-Pauker at the end of the 1950's and the beginning of the 1960's to sell power station equipment in third markets (India). The cooperation between Hungarian and capitalist firms to ship power station equipment to third markets has continued. We will quote from the aftermath those events that constitute a case study of the emergence of third market cooperation.

The order to supply gas turbine units to the Kelenfold steam power plant was awarded to Fiat Grandi Motori in cooperation with the Ganz Electric Works. This one-time cooperative project was developed by Transelectro into third market cooperation between the two firms lasting over a number of years. The number of gas turbine and diesel-fired power plant units delivered between 1971 and 1976 was 19 in Turkey, 6 in Finland, 2 in Dubai, 3 in Libya and 17 in Greece. Generators supplied by Ganz Electric Works represented 20 percent of joint deliveries, i.e., more than 10 million dollars. The cooperation among Transelectro, Ganz Electric Works and Fiat Grandi Motori reflects one of the typical features of third market cooperation, namely that getting to know one another through bilateral cooperation is one of the essential preconditions for third market cooperation. This also means that third market cooperation may correctly be called a more advanced form of cooperation. (It encompasses not only the production phase but also the preparation of proposals, joint marketing, joint venture, assumption of risks, financing, etc.)

Third market cooperation is interpreted differently in socialist and capitalist countries: capitalist firms in general consider joint tendering and joint venture as the only forms of third market cooperation. International economic organizations recognize many more types of cooperation in third markets, all of them justified. The experience of third market cooperation between Hungarian and capitalist firms also points to a wider range of forms.

The simplest and most frequent form is the purchase of marketing rights in third markets for cooperation or licence products. In the past we paid little attention to this but now we are increasingly taking care to ensure that production cooperation and licence agreements allow for sales in third markets. (And not just in CEMA countries.) For example, the Budapest Leather Industry Enterprise is producing upholstery materials based on know-how purchased from the West German firm Lingens and exporting them to third markets in advanced capitalist countries. The Telecommunications Materials Factory purchased ferrite production equipment and know-how from Krupp which has stopped ferrite production. The Hungarian enterprise is allowed to export to West Germany and third markets.

Subcontracting and Joint Proposals

A common form of market cooperation is the participation of capitalist firms as suppliers in the export of complete plant equipment. This does not simply mean that Hungarian foreign trade enterprises purchase and deliver the missing special machinery: they are already included in the proposal in cooperation with the capitalist firms. There are hardly any exports of complete plant equipment that do not involve such cooperation.

The reverse also occurs: capitalist firms may use Hungarian supplies or services (e.g., assembly work) in their exports to third markets. There is no denying that the examples of such types of third market cooperation are few and far between. Third market cooperation is usually suggested by Hungarian enterprises (this, in itself, presents no problem) and there are not many cases when capitalist firms suggest third market cooperation to them. There are few Hungarian enterprises with enough goodwill to make them desirable business partners. (The industrial background of Transelektro seems to be one: recently, a Dutch firm asked it to take part in the export of power plant equipment to Turkey.)

Joint tendering as a form of third market cooperation is not unknown in Hungarian experience. Hungarian foreign trade and productive enterprises involved in the export of complete and big-ticket plant equipment (Komplex, Transelektro, Ganz-MAVAG) are participating in public tenders with proposals formulated jointly with cooperating capitalist firms. To mention some recent examples: Chemolimpex and the Energy Management Institute are cooperating with a Dutch enterprise to sell desalination equipment in third markets and participate jointly in public tenders in Iraq and Algeria, while Chemolimpex, the Hungarian Aluminum Industry Trust and the French Kestner-Creusot-Loire are presenting a joint proposal for an alumina factory project in Jamaica.

The third market may be an advanced capitalist or a developing country. In practice, the third market is mostly a developing country. (In part because the need for complete plant equipment, turn-key factory or extensive infrastructural development project requiring cooperation among several cuppliers most often arises in developing countries. Furthermore, capitalist firms are more willing to cooperate with enterprises of socialist countries in developing countries than in markets that are already saturated.)

Trilateral Cooperation

For a number of reasons, developing countries consider cooperation between capitalist and socialist enterprises in their markets in a positive light. They think it is in line with their non-alignment policy. Socialist countries in general are willing to accept payment in kind; therefore, their participation improves the chances of development of large scale projects on a compensation basis. Nevertheless, developing countries do have some concrete expectations. They expect third market cooperation to be trilateral in one form or another. Since the majority of developing countries are not yet prepared to become suppliers or subcontractors, in most cases they merely require the employment of abundant local manpower in construction work. There also exist some full-fledged trilateral cooperative projects where the three partners are involved in joint production and marketing. With respect to Hungary, one might mention the bus assembly plant in Iraq where Ikarus bodies are assembled using Swedish Scania and French Saviem chassis. A similar kind of trilateral cooperative venture is envisaged in the Malagasy Republic where the Ikarus factory delivered 150 body kits so far in cooperation with the French Saviem; this was followed by the design of a midsize bus with Berliet engine and chassis based on a requirement of 900 buses. If the Hungarian and French companies can get the order then the assembly plant to be set up will turn this third market cooperative project into a trilateral arrangement. Hungarian enterprises are also participating in trilateral cooperative projects in other fields. (According to data compiled by EGB [European Economic Commission] and UNCTAD, 25 percent of the trilateral cooperative projects established in the course of third market cooperation in East-West trade involve Hungarian enterprises.)

The examples used to illustrate the various forms of cooperation in third markets provide only an indirect indication of the mutual advantages of this type of East-West cooperation: it provides marketing opportunities when the chances of either partner acting on its own would be less good. (In third market cooperation Hungarian enterprises are not only able to utilize the more

thorough market knowledge and better business relationships of their capitalist partners (often due to historical reasons); smaller capitalist companies are eager to participate in supplying our larger orders in developing countries. This also applies to other countries besides those that have less regular or developed economic and trade relations with their country than with Hungary.)

Intergovernmental Agreements

The principal and practical importance of third market cooperation between socialist and capitalist firms no longer lacks recognition on the intergovernmental level. The long range intergovernmental agreements between socialist and advanced capitalist countries include among their goals the development of cooperation in third markets. We also know, mainly from Hungarian experience, that joint committees are dealing with this problem every year. (In the Hungarian-Italian joint committee, a subcommittee has been established to investigate and initiate cooperation in third markets.)

Thus, the willingness for market cooperation is there on the intergovernmental, administrative and trade policy level. Yet, there are a number of obstacles slowing progress over a wider range of issues. On our side it is obvious that there are too few (and always the same few) enterprises able to take part ef ectively in third market cooperation. This indicates inadequate competitiveness and preparedness on the part of Hungarian enterprises in this regard.

To avoid all misunderstanding: it is not engineering or construction ability that is lacking. Let us note that the same kind of thing happened 10 to 15 years ago in the initial period of production and engineering cooperation. Enterprises, even the large ones, were slow or reluctant to enter into production cooperation with capitalist firms. The main reason was that this form of the international division of labor and international marketing is much more labor intensive in the preparatory and execution phase than plain exports. Most forms of third market cooperation are more complex and labor intensive than production cooperation. Concrete, not general, knowledge of the international field is needed. Business and possibly engineering and production relationships need to be developed with potential partners. Willingness to participate in third market cooperation must be explored. Proposals for joint participation in public tenders must be presented. It is even better when they are offering participation in business that has already been secured, etc. From the standpoint of foreign trade performance, third market cooperation is regarded as a form of export, but it is also a venture: an internationalventure which requires special aptitude and knowledge in the legal area.

The essence of the task arising from the foregoing discussion is that third market cooperation with capitalist firms must be incorporated into our foreign trade policy and, more importantly, practice, just as production and technical cooperation with capitalist firms on a bilateral basis has been incorporated earlier. This process may be accelerated on the level of economic direction. (It is already clear which third markets are most suitable for us and which sectors—product and development areas—are most promising for third market cooperation.)

Problems of Financing

The fundamental problem and limiting factor in third market cooperation with capitalist firms is that of financing. High priced plant equipment demands credit in every case. A substantial number of developing countries are using funds provided by bilateral credit and aid agreements fo finance development projects in progress. From the standpoint of third market cooperation with capitalist firms, such credits and aid funds can hardly be taken into consideration at all, because they increasingly exclude shipments from socialist countries or set a ceiling of 10 to 20 percent participation. The situation is similar when financing is obtained from private banks in Western Europe. Methods of financing by consortium can only cover their credit requirements associated with our own deliveries, in the best of cases. The Budapest international symposium also discussed the financing problems associated with third market cooperation. One proposal suggested the unification of credits and aid provided by various countries in a super-regional finance institution.

It would be difficult to assert that the present situation of and future outlook for third market cooperation with capitalist firms is promising or satisfactory. Even under such conditions, however, our goal must be to develop and expand such cooperation. There are many substantial reasons for this. Third market cooperation is an accepted and widely used method and form of international trade. A certain portion of our export potential (complete plant equipment and various systems incorporating engineering and intellectual creativity) cannot be marketed in any other way. It could also lead to a slight relaxation in the bilateral character of our foreign trade relations as a whole and the emergence of a rudimentary form of a multilaterality which characterizes the bulk of world trade. And there is one more practical argument: cooperation with capitalist firms in third markets increases export receipts in convertible currency.

PREREQUISITES FOR OPTIMAL INDUSTRIAL DEVELOPMENT DISCUSSED

AU181425 Budapest NEPSZABADSAG in Hungarian 8 Oct 80 p 10

[Article in economic column by Dr Mrs Laszlo Tuu, head of a department of the Central Statistics Office: "Large Enterprise, Small Enterprise: On Industry's Organizational Composition"]

[Text] The transition to intensive economic management and the requirement to improve the equilibrium of foreign trade and intensify efficiency, make it particularly timely to analyze the function of enterprise organizations and the system of their relations. Taking the experiences of the changes in the organizational structure to date and the conclusions that can be drawn from international practice, we are seeking an answer to the question of what composition and proportional size of productive organizations can create optimal development in various industrial areas.

Centralization Measures

Developing a modern domestic large-scale industry that is competitive even with that of the industrially more advanced countries has been a fundamental industrial-political goal of over 3 decades of our planned economy. Following the nationalization of industry, liquidating a broad array of fragmentary plants operating with low productivity was a most essential initial step toward this. Regrouping their machinery and productive equipment fostered a more rapid development of the more viable economic units. Also, the division of enterprises that used to produce a variety of goods into more homogeneous economic units, was a characteristic feature of the organizational modifications implemented at the beginning of the fifties.

In the first half of the sixties, the industrial enterprise organization was considerably modified in order to create, relatively rapidly, organizational prerequisites for large-scale production. As a consequence of amalgamations carried out in several phases, the number of state industrial enterprises decreased by approximately 40 percent. (In 1960 still 1,368, while in 1965 a total of 840 industrial enterprises operated as independent economic units.) A process of amalgamation of a similar dimension took place in cooperative industry as well, where the number of industrial cooperatives decreased from 1,251 in 1960 to 811 by the end of 1965.

Centralization measures were based on the--theoretically well-founded--notion that organizations possessing a larger intellectual and material base have a better

overview of the development tasks of the given industrial activity; with the knowledge of technical problems on a more extensive scale, can more clearly perceive the requirements of technical development; and in possession of more concentrated means, can more efficiently also resolve the research-development tasks connected with them. As masters of a given production sector, they can more accurately assess producer and consumer requirements and, in satisfying them, can act as equal agents vis-a-vis both foreign customers and domestic--also centralized--trade partners. In addition, the relatively small number of units pursuing economic activity also made direction easier based on direct instructions concerning the plan.

Experiences Abroad

As a result of the centralization that affected all industrial areas, our industrial organization acquired a characteristic composition that deviated from the internationally universal one. In quite a few branches, the entire activity of the branch was concentrated at one enterprise. In the overwhelming majority of branches, the number of enterprises decreased in such a way that the stratum of small and medium enterprises was greatly reduced or, in some cases, completely ceased to exist. Thus, in 1965, hardly 10 percent of state industry workers were employed at industrial enterprises with personnel of under 500 employees, and almost 35 percent of them belonged to the complement of enterprises employing more than 5,000 people. (By way of an informative comparison: at the same time, almost one-quarter of the Soviet Union's industrial workers, and more than 40 percent in the GDR worked at small and medium enterprises where the number of workers was under 500. The rate of enterprises with a staff exceeding 5,000 people was below 30 percent even in the Soviet Union, while it barely exceeded 10 percent of the overall complement in the GDR.)

The organizational composition of the capitalist countries' industry also differs considerably from the proportions that have developed in our country. Comparison results show that not even in countries with an advanced industry does one come across a withering away of the small and medium enterprises strata. In their entirety, these constitute a considerable portion of the industrial organizations of the reviewed countries. It is obvious that the sphere of small capitalist enterprises and their area of activity are more variable than the average, because, owing to being less endowed with capital, they are less able to fend off individually the effects of a recession. However, their relatively stable proportion within industry indicates that their activity is required by economic life and those that are discontinued are continuously replaced by new small enterprises.

Enterprises With Many Separate Plants

In the years immediately following the 1968 reform of the system of economic direction, the decrease in the number of state industrial enterprises did not continue in our country, and the area of cooperative industry even expanded (mainly the number of joint industrial ventures established by agricultural organizations increased). Then the process of organizational changes in the industry picked up in the seventies. The new reorganizations were based overwhelmingly on enterprise initiative: for the main part, large-scale enterprises absorbed into their own organization smaller enterprises (most of which used to be directed by councils) with which they had cooperative relations before. In 1979, as a

result of these changes, 702 enterprises belonged to state industry and 670 organizations pursuing economic activity operated in the cooperative industry. Approximately 230 of the above state enterprises conducted their economic activity under trust direction.

Many of our large-scale industrial enterprises conform well to the requirements imposed on their operation. They have successfully accomplished the preferential development programs serving the transformation of the production structure. They actively participate in cooperation with regard to specialization and joint ventures among the CEMA countries and, through their direct linkage with foreign trade activity, they can react more rapidly to foreign market requirements and are thus--as a result of intensifying their exports and conserving imported materials--effectively contributing to improving foreign trade accounts.

However, in another respect, negative economic effects also arise from the present structural composition of our industry. These manifest themselves mainly in diminished possibilities for cooperation, the supply of products and joint ventures among productive enterprises; the undeveloped nature of back-up industry engaged in specialized activity; and an increase in the number of components and consumer goods that are in short supply temporarily or constantly.

In my opinion, a large portion of these problems can be traced back to the fact that the process of centralization has extended also to areas where adapting to demand by users or consumers and ensuring a broad structure of supply in a flexible manner justify the existence of small and medium enterprise organizational forms. As a result of the fact that new large-scale industrial organizations came about, in general, through absorption of small enterprises, the "many-plant" enterprise form has become predominant in our industry. (In 1979, taking state industry as a whole, there were on the average seven industrial plants per enterprise. Regional dismemberment has increased most in the machine industry, where, as compared with 1960, the number of industrial plants per enterprise has more than trebled and their present rate is higher than the industrial average.) The direction of a large number of productive units, which are sometimes regionally fairly far from each other, inevitably slow down enterprise reaction and diminish local initiative ability as well.

What Changes Are Required?

Consistent with worldwide industrial development, the large-scale enterprise pattern must constitute the basis of our economic development also in the future. However, to complement the activity of large-scale enterprises, greater scope than at present should be extended to small and medium enterprises capable of fairly flexible economic activity.

It is useful to retain the large-scale enterprise organizational form or regard it as a goal of development primarily in areas and with regard to economic activities where:

--Great fixed asset intensiveness characterizes production,

--Profitability of production is subject to a large volume, and

--There is a rapid technical development on a world scale, as a result of which a great concentration of research and development resources are required.

On the basis of these criteria, obviously the large-scale enterprise form can be continued to be considered in the case of exploiting (mining) and raw material producing activities. In these areas, the need for considerable investments makes the utilization of the advantages of centralized enterprise direction on the one hand, and a more coordinated surveyance and satisfaction of the requirements of customers on the other hand, indispensable as well as possible by virture of production processes that change only to a small extent in the long term and a relatively stable product structure.

However, what can be regarded as desirable in the processing industrial branches is that various forms of enterprise organizations, large-scale as well as small and medium enterprises, pursue their activity in cooperation, and at the same time in a sound competitive spirit. Here also, satisfying mass requirements (production in large series) has to fall to the competence of large-scale enterprises in general. However, smaller organizations able to undertake economically a more flexible changing of the range of products and production in small series, will have to be assigned a greater role in areas that require prompt adaption to special demands and consumer requirements (for instance, fashion).

The economic self-sufficiency of units of enterprises with many plants that are operating without suitable efficiency, units separated regionally and also with regard to their sphere of activity, is only one means for strengthening the small and medium enterprise stratum. In addition--as was noted also at the latest session of the National Assembly--the government intends to encourage the proliferation of organizational forms that will provide the means for establishing new industrial productive units, primarily within the framework of cooperative associations. Overcoming problems of financing connected with this and creating more flexible conditions for accepting work could thus considerably ease the task of making good the present production shortages and the development of a more proportional organizational composition of industry enterprises.

CHANGES IN AGRICULTURAL FINANCING: ECONOMY, EFFICIENCY STRESSED

Budapest FIGYELO in Hungarian 5 Nov 80 p 13

[Article by Rezso Kostyal: "Revenue and Incentive"]

[Text] In the nearly 1 year period since the operation of the price and financial regulators which were established in 1980, determined efforts have been made on the large farms to use less energy-intensive technologies and modify the production structure in a way aimed at countering the factoring-in costs. Manpower and wage management experiences have also been favorable. In the elapsed time, however, it has not as yet been possible to filter out the experiences which basically characterize the entire operation of the regulatory system since the large farms have not as yet prepared their midyear balance reports, and data characteristic for the whole year are not yet available.

Instead of Special Supports

On the basis of all these things, we needed only minor corrections and changes, as justified by experience thus far, in establishing revenue regulations for 1981, excepting supports for construction investments. In respect primarily to its system of measures, the latter cannot fit into the estimates for the Sixth Five-Year Plan, and its operational system cannot be maintained under the altered conditions.

In the first half of the Fifth Five-Year Plan period the support system for agricultural investments appropriately helped in the coordination of farm and national economic goals. But as early as 1976-1978 they exceeded the plan investment targets of the large farms by about 15 percent, and the structure of construction investments gradually shifted toward those goals which specifically shared in higher supports. At the end of 1978 this process made it necessary to limit the publication of investment support documents. Bu this time, however, the stock of investments underway had significantly increased, and their investment requirements, together with the newly started investments, exceeded the sum targeted in the plan. Despite the partially limiting measures still in effect in 1980 about half as many again of planned supports will be negotiated this year. Thus as of June of this year it was not possible to grant further supports. Expressly, cost-saving quarters for pigs, milking cows and sheep could be built by means of supports only within definitely limited sums, and these too only on the basis of competitions announced under special conditions.

In the first half of the Fifth Five-Year Plan period the support system for agricultural investments appropriately helped in the coordination of farm and national economic goals. But as early as 1976-1978 they exceeded the plan investment targets of the large farms by about 15 percent, and the structure of construction investments gradually shifted toward those goals which specifically shared in higher supports. At the end of 1978 this process made it necessary to limit the publication of investment support documents. By this time, however, the stock of investments underway had significantly increased, and their investment requirements, together with the newly started investments, exceeded the sum targeted in the plan. Despite the partially limiting measures still in effect in 1980 about half as many again of planned supports will be negotiated this year. Thus as of June of this year it was not possible to grant further supports. Expressly, cost-saving quarters for pigs, milking cows and sheep could be built by means of supports only within definitely limited sums, and these twoo only on the basis of competitions announced under special conditions.

In harmony with the changes in certain elements of the price and regulatory system, the modifications which were put into effect this year significantly reduced the variations in the supports extended to construction and new planting investments. The intent was that the development activities of the large farms should be influenced not by special supports but primarily by efficiency, more rapid clearing costs, and in general operational advantages in harmony with the interests of the economy. This goal was served by the order according to which a broad-scale basic support was realized for investments, and the large farms were able to ask for special supports to attain economically important production goals.

In harmony with our possibilities, the financing system can promote the realization of our goals if there is an increase in the ratio of the more selective and flexible credits instead of supports than can be used automatically. By this means it is possible to avoid the development of investment peaks, and in the knowledge of the conditions of their planned development the farms can decide on the use of the development monies available to them. Beginning in 1981, construction investments in agriculture also will be realized mostly from the farms' own financial sources and from credits. Thus in new construction investments the credit worthiness of the farms, the profitability attainable in planned investments, and generally the cost recovery time will play a greater role.

What the Large Farms Must Make Up

The interest on credits for construction investments is identical with those fixed in the guidelines. Because of the termination of supports for construction investments, the budget extends interest reimbursement for interest costs that are generally increasing on large farms. In harmony with the special development goals of the plan, the interest reimbursement may be of different (varying) degrees on the extended credit but at most on 70 percent of the qualifying investments.

State supports for pig-breeding and dairy facilities will be maintained to a lesser extent than before. This is necessary on one hand for basic material supplies on behalf of pork-processing facilities that have been built or are on the way, and on the other hand because the level of milk and dairy supplies can be maintained only if the large farms make up for the reduction of cow stocks which has taken place on the small farms in a way at variance with our intention, but something that is inevitable with the change in village lifestyle. These supports can be requested

not only for new buildings but also for modernizing existing ones. An essential difference from previous practice, however, is that the farms do not receive the supports in advance but only after the investments have been put into operation. If a large farm receives credits for the above-mentioned investments, the repayments on the credits for investments used afterwards must be proportionally reduced. This order gives incentive to the large farms to reduce the implementation time of the investments, and the unjustifiably large stock of unfinished investments may also be moderated.

The rules for investment support on behalf of new planting areas remain unchanged. This is justified by the fact that the implementation time for new planting areas is long, it is extremely capital intensive, and because there are important national economic interests linked to the continuous modernization of planting areas.

Amortization on Gross Value

In harmony with the modification of the financing system, there is a change in the regulation of depreciation write-off and the use of the development funds. The system of depreciation white-offs for buildings remains unchanged, while for fixed assets created according to the new financing system, excepting pig-breeding and milk production facilities, the amortization must be calculated according to the full cost, that is, on gross value. In the use of the development fund the obligations in effect up to now for producer cooperatives will be terminated; that is, in accordance with the farm decisions the amortization may be used both to replenish the circulating fund and repay credits as is the case with state enterprises.

The effect of the new price formation introduced in 1980 is significantly influencing the price and financial conditions of food production, although in this area competitive price formation has not been realized. In most of the purchasing price changes, the automatic realization of midyear price changes for materials of import and industrial origin used in agriculture does not seem justified given the present economic conditions. The biological factors which determine production in crop raising generally mean a production process of 1 year, and in the most important branches of animal breeding a production process of several years. Therefore, frequent midyear changes in producer prices would influence management disadvantageously and cause uncertainty in incentive relations.

The 1980 producer price increases for the most important materials of industrial origin used in agriculture (fertilizers, herbicides, fodder) and machinery were countered in midyear by budgetary supports. The rise in energy prices, on the other hand, increased farm costs, and gave incentive to energy savings. On most of the farms the significant rise in energy prices could be countered over a year only partly by a rational reduction in consumption, and a midyear modification in the official purchasing prices did not take place; therefore, the large farms can request budgetary subsidies to the end of the year for a greater portion of the cost increase.

The already announced 1981 agricultural producer price increases cover temporarily extended budgetary supports, taking also into account the realistically attainable improvement in efficiency. In connection with the above, the support indexes are changing, generally declining, for machinery, fertilizers and herbicides, and the withheld import and industrial producer price increases for 1980 are already being realized in the agricultural purchase prices.

The farms must prepare themselves for more frequent price changes in this sector than has been the case in the past by adjusting to the above-mentioned agricultural characteristics. Obviously, the cause is the fact that the import or industrial producer prices of basic means and materials used in industry are following the constant price changes on the world market, and it is justifiable to realize these changes on the world market, and it is justifiable to realize these changes also in farm costs, naturally in harmony with purchasing price increases. Import and industrial producer prices may change more than once a year, while it is purposeful to change the official producer prices for agriculture only once a year. Depending on the revenue situation in agriculture, it becomes the task of the financial system to assist in the smooth financing of production up to the settling of purchasing prices by moderating the cost of increasing price hikes for basic materials and means with midyear and temporary supports.

The effect of producer price increases varies on farms with different endowments: the price increase for materials and means of industrial origin is countered to a smaller extent by the price receipt increase attainable with lower yields on poorer productive soils than on favorably endowed farms. In view of the fact that in the differentiation process among farms the efficiency differences are determining, we must strive to develop, together with the differentiation effect of central measures, such economic conditions as will make the economic development of this group of farms possible from their own resources. With a greater degree of purchasing price increases in 1980, such measures were undertaken with the land tax, revenue tax, and production tax. The 1981 average purchasing price increase of 5 percent has to a lesser extent justified changes in two areas; on farms where the average cadasteral net income of the arable area is between 14 to 19 gold crowns, the land tax payment requirement is eliminated. The exemptions that existed up to now will remain. The subsidy for withholding the production tax--over and above the farms listed as being unfavorably endowed--can be used up to 30 percent for farms with an arable area below 19 gold crowns in value.

Household Farm Assistance

Experience shows that an increase in slaughter beef production is primarily a function of economic export possibilities. Economic analyses clearly establish that this can be attained with well selected, meat enriched types or hybrids, minimal fodder-intensive technologies, and the use of grass areas, economic by-products and rough fodders. In the case of such development, the greatest burdens for the farms are represented by the acquisition and raising of cow stocks, or its circulating fund demand. For this, the large farms receive 20,000 forints per head support in event of a constant increase in the meat cow stocks, independently of quarters expansion. Experience shows that supports for establishing and renewing fields and pastures have not been accompanied by the expected results, and therefore these supports are being gradually eliminated.

The state is continuing financial assistance to household and small-farm production, and in certain branches to increased production as well. To promote mechanization, the scope of small machines that share in supports is being expanded, and farms that have a number of cows receive a 1,000 forint greater support for the second and every additional cow.

The system of earnings regulations for large farms changed significantly on 1 January 1980. The effect of the new rules cannot as yet be comprehensively evaluated, but the available money data show that the fee and wage management on large farms has become more considered. The sum of midyear wage payments rose to a lesser extent than a year ago, and therefore apparently even in case of an increase in year-end premiums and shares, revenues will remain within the planned limits. Thus basic changes are not justified in the system of fee and share taxes, the changes occur with the measuring system.

Farm Incentive

The unfavorable effect of average wage regulation was not solved by the subsidy which in management within a work-fee bill made possible a more than 1 percent rise in the work-fee level. It did not provide enough incentive to the farms to employ the relased manpower by the use of more modern technologies or work organization in work areas of similar efficiency, or to cut back personnel. Therefore, the above-mentioned 1 percent subsidy rises to 3 percent in management within the work-fee bill. It is a minor but not insubstantial correction which makes it possible for all profitable large farms to pay at least 1 percent of the work-fee bill, tax free, as a year-end share, if the money cover is available.

In construction-fitting work and in services a problem existed, besides the varying consumption, in that the basis of profit formation and the production tax was different. The change, therefore, is directed at requiring that the production task be paid on material-free price receipts, instead of the price receipts, according to indexes changed by activity. A further modification is represented in the production tax system by the fact that the large farms, with the 1980 rise in specific production prices, will pay the differential producer sales tax in the future as a production tax. Thus this withholding is built into the producer tax system.

The development of industrial activity by the farms and the improvement in industrial cooperation conditions is served by an order which provides that in the future when making use of the production tax withholding subsidy large farm payment of an agglomerate separate tax will not be an excluding cause.

The agricultural regulator changes which will be valid in 1981 take into account the development circumstances of our economic development, and raise requirements particularly in the investment field. As a whole, on the other hand, they promote development of the rational initiatives which by improving the quality indexes of production adjust to the internal and external economic conditions.

MAV'S FUTURE UTILIZATION OF DIESEL TRACTION DESCRIBED

Budapest VASUT in Hungarian No 8, Aug 80 p 7

[Article by Istvan Mezei: "The Future of Diesel Traction"]

[Excerpt] The modernization of traction will continue at MAV [Hungarian State Railways] during the coming period, but the development will not be as visible as was characteristic of the 1960's.

The future of diesel traction will be determined by the rate of electrification and the planned elimination of steam traction in 1985.

At the end of the Fifth Five-Year Plan, the length of the electrified rail network will be some 1,500 kilometers, and about half of the transportation performed by MAV will take place over this network.

The length of electrified track in the Sixth Five-Year Plan is about 3,000 kilometers. At the end of this plan period, in 1985, some 20 percent of the network will be electrified, and the share of transportation using electric traction will be about 60 percent.

According to MAV's long-range development plans, by 1990--the end of the Seventh Five-Year Plan--out of the 3,000 kilometers in the main network, about 2,400 kilometers will be electrified, which is between 32 and 34 percent of the present total network.

It is worth noting that according to plans three fourths of total transportation performed will take place over the electrified network.

The tasks of pulling and switching now performed by steam locomotives will be taken over by diesel or electric locomotives. The tasks of diesel traction will be determined by electrification of the lines and cessation of steam traction, but there will be no change in their nature, since diesel traction is presently suitable for performing all the pulling and switching tasks.

The amount of work done by the steam locomotives is less than the increase in work done by the electric locomotives; hence the share of diesel traction in transportation over the main lines will continue to decrease.

With the cessation of steam traction, complete modernization of the switching operation will be completed. In 1979, 13.2 percent of the switching was done by diesel locomotives. According to preliminary plans, 95 percent of the switching will be done by diesel locomotives in 1985 and 90 percent in 1990. The decrease is the result of the fact that under the Seventh Five-Year Plan electrification of the switching locomotives is expected to begin.

According to domestic calculations, the economic life of diesel locomotives is estimated at 25 years. Because of the limited funds available for investment, however, this cannot always be realized. One result of this is that costs for maintenance increase. Presently there are 12 kinds of diesel engines and 4 kinds of motorized cars in operations on the standard gauge lines. According to plans, the M.28-series locomotives will be phased out by 1985 as well as some of the M.31-series locomotives and the AB, ABny, ABb, and Eb motor cars.

Dur[illegible] the period of the Sixth Five-Year Plan, only M.41-series diesel locomo[illegible] will continue to be acquired. Among diesel locomotives for switching, acqu[illegible]on of M.43 and M.47 series locomotives will continue; it is expected to be completed by 1985. In addition to performing light and medium switching tasks, these locomotives are also suitable for carrying trucks.

Diesel traction in MAV during the past 5 years has been an important means of modernization. Because of the energy situation and the many other advantages of electric traction, beginning in the middle of the 1980's--the work performed by diesel locomotives will decrease. On the branch lines and in switching service, however, diesel traction will continue to be critically important.

ROLE OF SELF-MANAGEMENT IN IMPROVING FUNCTIONING OF SOCIOECONOMIC SYSTEMS

Bucharest REVISTA DE FILOZOFIE in Romanian No 4, Jul-Aug 80 pp 395-400

[Article by Haralambie Ene: "Self-Management as a Principle for Increasing the Functionality of the Economic and Social Systems"]

[Text] In the Romanian Communist Party's view, self-management expresses a basic principle in the management of society, a consequence of the objective tendencies of continual development of worker democracy, in the prospect of turning--as it is pointed out in the RCP program--to "...the achievement of the higher, communist form of the management of society by the masses, to the forging of history by the people, in accordance with their own will."* The whole activity of direct participation by all the working people in the practical management of the economic and social units, in the concrete preparation of the decisions and strategies on development that they must carry out, is based on this principle.

A thorough analysis of its content shows that self-management is not confined to the mere expansion of the participation in management, to the numerical growth of those who take part in the act of decisionmaking within the economic and social units. Its aspects are many and have consequences on very different planes of social practice.

Thus, as a principle of the scientific management of socialist society, self-management is seen, firstly, as a political principle, directly involving the basic values of the new order, the affirmation of the class interests of the working people. From this viewpoint, the application of the concrete forms that give life to the principle of worker self-management has in view:

The growth of the role of the working class in the whole process of management of society and its subsystems;

The strengthening of the role of the Communist Party and its organizations in the management of all aspects of economic and social life;

* "The Program of the Romanian Communist Party for Forging the Multilaterally Developed Socialist Society and Advancing Romania Toward Communism," "Congresul al XI-lea al Partidului Comunist Roman" [The 11th Congress of the Romanian Communist Party], Bucharest, Politica Publishing House, 1975, p 720.

The continual development of worker democracy, by expanding the collective character of management in all fields of activity;

The fuller and fuller manifestation of the personality of the working people, by directly involving them as participants in the management of social life;

The releasing of all the creative energies of the masses of working people, as a basis for increasing the efficiency of their social activity;

The raising of the degree of responsibility of the working people through their direct participation in making the decisions, which they are called upon to carry out as their own decisions.

All these things demonstrate the primarily political character of self-management, with profound implications for the revolutionary role of the working class and its party, for the personality of the working people as future builders of communism, and for all ideological and educational activity.

At the same time, the analysis of the content of worker self-management and self-administration also makes evident, besides its political, class essence, a factor of an economic nature, which has been the basis for promoting this principle--namely the one referring to the necessity of increasing the level of efficiency of management as such.

By means of its polyvalent character, this principle is also constituted as a factor for optimizing all social activity,* having as well a pronounced functional content, manifest--due to the economic and social mechanism that operationalizes it--on the plane of the activity of all the economic and social units. While its political aspect emphasizes its revolutionary, class character in the development of our society, its economic aspect involves the growth of the functional character of all economic and social activity, lays the foundations for new levels of efficiency, constitutes an important step toward a new quality of labor in all fields. The following relations are involved here:

a) The bringing of the decision nearer to the level of production, by increasing the autonomy of the basic units and widening the powers of decisionmaking on their own problems. Management by petty surveillance is thus avoided and the capacity to give suitable answers to the particular problems with which the unit is confronted is developed, with all the positive consequences that arise on the plane of functionality;

b) The stimulation of one's own effort, which permits the matter of utilizing to a greater extent, in the spirit of efficiency, all the internal reserves, all the technical and human capacities that sometimes remained in a dormant state;

c) The growth of the level of "operationality" of management, of the decision, and of guidance of the activity in itself, the growth of the system's speed of reaction to the stimului exerted by the requirements of the other systems as beneficiaries,

---

* See: Aneta Nutu-Busuioc, "Self-Management, a Method of Optimization of Social and Human Activity," REVISTA DE FILOZOFIE, No 5, 1978.

which constitutes the basis for increasing the functionality of the units and eradicating inertial and bureaucratic phenomena;

d) The accenting of the dependence of the managed systems on the requirements of the social needs and not on the hierarchical factors, by reducing the possibilities of making the unit autonomous with respect to the social function that devolves upon it;

e) The institution of full agreement between activities and results, between effort and effects, the latter being much more clearly individualized and put in relation to the achievement of the social function with regard to which efficiency is now measured.

In fact, the principle of worker self-management and self-administration includes both the strictly political, ideological, class aspect and the functional and operational aspect that offers to all the economic and social systems the means needed for performing their activity in terms of much higher efficiency. Moreover, it is known that, in the process of putting this principle into practice, there has been taken into account precisely its great capacity to conduct our society toward a new, revolutionary stage on the way to the construction of communism and, at the same time, toward a new level of efficiency in management by increasing the functionality of the activities in all fields of social life. "By means of the measures established," it is pointed out in the Decision of the RCP Central Committee on the Improvement of Economic and Social Management and Planning, "there has been created a widely democratic framework for the participation of those who work in the management of the national economy and all social life, so that each work staff may fulfill its role in the proper running of the unit in which it works, in order to increase economic efficiency, to raise the standard of living of the masses, and the general development of society."*

At the same time, there has also been devised and put into practice the concrete mode of objective connection between the requirements for satisfying the social needs, on the one hand, and the intrinsic capacity of the managed subsystems to develop a sufficiently high speed of reaction in the process of distinguishing these requirements, in adjusting their own structures in relation to the content of the requirements and then in the actual response that the system must give to these needs, on the other hand. Practically, as Comrade Nicolae Ceausescu pointed out, it is a question "...of raising the economic and financial mechanism to the level of the development of the new forms of collective leadership...,"** of imposing on the activity of managing all fields of economic and social life a unified system based on the principle of self-management and operationalized by an economic and financial mechanism capable of utilizing all the potentialities of efficiency that the

**Nicolae Ceausescu, "A Speech at the General Assembly of Working People at the Bucharest Heavy Machinery Enterprise, 16 February 1978," "Romania pe Drumul Construirii Societatii Socialiste Multilateral Dezvoltate" [Romania on the Way to Constructing the Multilaterally Developed Socialist Society], Vol 15, Bucharest, Politica Publishing House, 1978, p 524.

principle in itself entails. In this way, the theory and practice of scientific management in our country have found themselves the most efficient tool by means of which it is possible to arrive at the growth of the functionality of the economic and social systems, at the eradication of the forms of seclusion and inertia in the activity of economic and social units, concomitant with achieving the highest precepts of the development of democracy, the participation of the working people in management, the as full manifestation as possible of their personality and creativity.

In this perspective, the affirmation of the principle of self-management and self-administration and the application of the economic and financial mechanism do not involve just a mere increase in degree in the autonomy of the units, an "autonomization" in the sense of weakening the imperatives of unitary management, nor is it a question of the weakening of the planned character of the activity or, eventually, of the creation of premises for the affirmation of the narrowminded local interests to the detriment of those of a general order, but of a revolutionary change that, emphasizing the role of the internal forces of organization and decisionmaking, seeks to more closely connect the activity in the managed subsystems with society's real requirements, to cause an increase in their speed of reaction. Self-management seeks to lay the foundations for high functionality on the economic and social plane and to achieve the performances of efficiency to which the structural superiority of the socialist order entitles us.

For this, the principle of self-management modifies the relations of responsibility, in the sense that it accentuates to a greater extent the direct responsibility of the unit and the staff of working people for the concrete economic and social necessities that society affirms. The feedback that connects the system of action with its social function is now constructed better and can mediate relatively rapid corrections in the structures of action in the system, the blocking of the tendencies to shift the objective, of the formalistic proliferations in records and in the organizational structures, and of the old-fashioned mentalities. Responsibility, too, appears even more clearly shaped and individualized and can no longer be masked by means of discussions, justifications, exceptions coming from the higher bodies, but is expressed directly in the means that are the basis of the continuation of the unit's activity, of its financial capacities.

Seen from the angle of the functionality of the economic and social units, the principle of self-management also involves another important aspect—namely the raising of the level of conscious action of the working people. The documents of the Romanian Communist Party and the entire analysis in the specialized literature show that, for example, the obstacles that the various concrete forms of manifestation of bureaucracy produce are not due exclusively just to the structures that determine more or less objectively a certain behavior, but to the type of action that is developed as a result of individual models of thought, of understanding and of political and professional consciousness. Consequently, the eradication of these inertial forms does not refer just to the perfecting of organizational structures (for example, those that refer to normativeness, authority and control), but also to the aspects that refer to the own behavioral models of the people integrated into these systems of action. The attack on the poorly functional phenomena is successful if there is also an emphasis in the direction of changing the mentalities, of stimulating a means of more directly relating to the requirements of management, to its objectives, which also follows the principle of worker self-management and

self-administration. The transition from "the administration of the unit" to the unformalistic cooperation of all the working people on the basis of a unitary understanding of society's requirements, the transition from formal relations of subordination to the participation of all on the basis of high professionalism, from conformist control to an operative spirit, to self-control and the understanding by each working person of the necessity and purpose of his activity, at bottom, of the social values that he must embrace—these are the ways that this principle makes evident for increasing the efficiency of management.

Self-management thus proposes extremely important objectives on the very plane of transforming the people themselves, the political, professional and social consciousnesses in general. As a solution for eradicating the inertial forms in time, this principle involves, in the future, the elimination of the inertial and conservative mentality, of the tendencies of disinterest and minimization of one's own effort, all these things also being so many possible causes of dysfunctionality. The whole process of improvement in economic and social activity through the affirmation of self-management and self-administration involves the stimulation of one's own effort, of the efficiency of one's own action, on the basis of continually developing the political and professional consciousness of all the working people.

By means of this there are created conditions for the process of management in the economic and social systems to no longer be confined to the strictly administrative plane, to no longer seek possibilities of minimizing the effort and yield easily to dysfunctional tendencies, but, on the contrary, to seek a permanent alignment with society's requirements on the plane of efficiency and functionality.

In this sense, as an operational tool, the possibility of personally preparing the plan, starting at the bottom, from the directly productive systems, as a basis for planning all economic and social life, makes a significant contribution. Thus, the unit in question is subordinated—from a functional viewpoint—to the social needs to a greater extent, which it was called upon even before to satisfy, but with evasion by changing the objectives or minimizing them being impossible for it. As Comrade Nicolae Ceausescu pointed out, it is necessary for "the plan for economic and social development to be drawn up by each enterprise and unit, starting from the production capacities that it has,"* which means that—under the conditions in which the unit's activity is evaluated according to the indicator of the volume of net output and physical output—each managed system should be interested in utilizing as fully as possible these capacities, the human and material production forces with which it is equipped.

Another specific relation in which the economic and social systems are put under the conditions of self-management and self-administration and which can create to a greater extent conditions for growth in functionality is the contractual relation. The contract, as a legal expression of the relations between units, now imposes the the closer connection of the activity in the managed systems with society's needs from a physical viewpoint and no longer permits the changing of the purposes, disinterest in the real requirements of the beneficiaries, at bottom, of society. The contractual relation existed even before, but under the new conditions it is strengthened in the sense that, as Comrade Nicolae Ceausescu pointed out, all

* Ibidem, p 525.

productive activity must now be done "...only in relation to the consumption necessities of the population, to the requirements of the domestic and foreign markets. Consequently, I have also said," the secretary general of the party pointed out, "that an enterprise can produce only what responds to the real necessities of the people, decisively combating any waste. It is necessary for us to take into account the demand and to offer the products that society and the people really need. Let us not allow any kind of production that is not wanted by society, just for the sake of producing."*

Self-management, from the viewpoint of its operational and functional aspect, could not be put into practice without another attribute that devolves upon all the economic and social systems—namely the preparation of one's own income and expense budget, a factor by means of which self-administration takes place, mediating the creation of the financial capacities for supporting the unit's activity in the future. The budget continually offers the picture of the content of efficiency of the activity of the managed system, constitutes the result of the feedback between this activity and the way in which a response has been made to the concrete requirements of society. The budget, as a tool for measurement, creates at the same time the possibility of controlling with greater efficiency the perturbations that can derive from the entropic tendencies of the structures of action, is a factor that stimulates the more efficient utilization of the units' own capacities, the growth of the level of functionality of the units.

All these things are the basis for the appearance of a new tool of management—namely the self-financing of the activity performed, which constitutes another specific relation into which the unit enters in the process of self-management. Self-financing contributes essentially so that the system in question frees itself from the dependence on the hierarchical structures in themselves (that of control and unitary coordination will still remain, of course) and enters into a very close dependence in relation to the social function that it must satisfy, because only as a result of this satisfaction can the resources needed for continuing the activity also be obtained. On the plane of concrete activity, self-financing presupposes a number of elements that strengthen the objective tendencies of the managed economic and social systems toward functionality, in the sense that:**

a) It involves the meeting of the production and circulation expenses from one's own accounts;

b) It obliges the repayment to society of the funds received for the supplying of means of production;

c) It involves the unit in participating in the formation of the centralized funds, then redistributed in the process of the multilateral development of the whole society;

---

* Idem, "A Speech at the Plenum of the National Council of Working People, 26 April 1978," op. cit., Vol 16, Bucharest, Politica Publishing House, 1979, pp 131-132.

**See: A. Sesan, "An Efficient Framework for the Affirmation of Self-Administration," REVISTA ECONOMICA, No 2, 1979, pp 9-10.

d) It induces the unit to form its own development funds;

e) It permits material incentives for the staff of working people through the formation of funds corresponding to this purpose.

The whole activity of the units is thus supported to a greater extent by the results of their own effort, and the management is induced objectively to maximize these results, to seek the means of increasing this effort, in the last analysis, to take all the steps to raise the level of functionality of the system, to eradicate its inertia and routine, bureaucratic and formalistic tendencies.

Finally, the promotion of the indicators for measuring efficiency by means of net output and physical output, and profit sharing, constitute, together with the factors analyzed above, a framework of new powers and relations with a role of stimulation for economic and social activity in the direction of more fully satisfying the social needs, bringing the real capacities of the system into agreement with its social function.

As a result of putting the principle of self-management into practice, a response is made at the same time to important objectives that are pursued by any process of managing a socialist unit that tends toward economic and social optimality, namely:

a) The concentration of manifold capacities of creativity, of different experiences, which means that, right from the start, a decision's chances of attaining the desired level of optimality and thus of functionality increase. In fact, society thus utilizes in a much more economical way its resources of intelligence, creativity and initiative, which would otherwise remain in a dormant state, unactivated;

b) The wide and effective participation in decisionmaking helps to raise the level of general responsibility of the working people, to involve them more deeply in the process of attaining the objectives provided by the decision whose makers they feel themselves to be, reducing, on this basis, the possibilities of manifestation of bureaucratic practices. A stronger motivational system for their actions is thus created. In this way, there are avoided the difficulties that appear as a result of communicating and transmitting within a staff of working people a decision whose sense it hardly has to grasp and whose objectives hardly have to be explained;

c) At the same time, the act of participation also involves the attainment of an objective of a social nature, in the prospect of which participation appears as one of the most effective means by which there occurs the process of multilateral development of the personality of the one who participates and who can thus express himself more completely and efficiently, as a producer, of course, but also as a decider, an owner, therefore, able not only to carry out orders, but also, on the basis of a personal act of choosing, to propose new structures and actions, new solutions.

These structural improvements in the management process start from the basic idea that efficient activity is determined, firstly, by the possibility of manifesting one's own internal capacities for analysis of the problems that one must overcome, by the manifestation of the working people's potentialities of creativity, by the behavior of the managed system as a self-regulating system. In this sense, the main efforts of the system will be concentrated not in the direction of devising

responses that the tutelary relations imply under the conditions of the excessively centralized decision (therefore, of simple feedback of a hierarchical sort), but in the direction of satisfying the requirements that society presents to the system in question, determining objectively the tendency toward effective functionality and not toward formalism. The activity of management, far from still being tempted to try justifications, postponements, the prevailing of formal aspects, possible in the case of the preponderant existence of hierarchical feedback, must now concern itself especially with the way in which it is necessary and possible "to solve in the last analysis the problems regarding the deciphering and summation of the social needs, the defining of the relations between needs and interests, the selection of a set of methods for attaining the objectives"* and, therefore, with the way in which the system can be made more functional.

The element on which the basis will have to be put is the initiative of the respective management body, under the conditions in which the unit is now equipped with all the means, from the material ones to the decisional ones, needed for achieving the objectives desired by society. The principle of self-management and the new mechanism of action and decisionmaking permit a more correct evaluation of the results according to the actual contribution that each staff makes, according to the personal effort that the unit makes.

Through the measures for perfecting the mechanism of management, through the irresistible affirmation of the creativity of the masses of working people called upon to participate in the whole decisional process, through the devising of the bases of worker self-management and self-administration, our party has again turned out to be the most revolutionary factor in social and political life in our country, capable of analyzing, in their dialectical evolution, the structures of action existing at a given time and of devising the most suitable forms for turning to a new stage of efficiency.

Of course, in our party's view, the putting of all economic and social life on the basis of self-management and self-administration, the putting of the economic and financial mechanism into practice, is an evolutionary process, in the sense that it did not end along with the devising of this mechanism, but, in fact, began then. Equally, the growth of the level of functionality of our economic and social systems and the disappearance of inertial phenomena, too, have a processual character. We cannot say that through the theoretical devising itself of these measures and their introduction into practice we have already solved all the problems that are posed on the plane of the functionality of our units, but these measures, surely, are bringing about the objective conditions for developing tendencies of growth in the interest in increasing the own effort, the initiative of the wide masses of working people. Of course, as Comrade Nicolae Ceausescu stated, these measures "...for improvement in economic and financial management, for achievement of a better economic and financial mechanism, have a special importance. However, I point out," the secretary general of the party specified, "that they constitute merely the suitable legal, economic and financial framework. No one should expect miracles just through the very adoption of these decisions. In order for them to give the results that we desire, we must act with all possible steadiness to implement them rapidly and in

* Ion Mitran, "Democratic Centralism and Worker Self-Management," ERA SOCIALISTA, No 7, 1979, p 11.

the best way...."* It is important that these complex measures, by developing the forms for involving the masses in management, by increasing the direct responsibility of the units and the working people for meeting the requirements of society, can effectively lay the foundations for much more functional and much more efficient economic and social activity, creating the objective framework for attaining those performances that the structural, organizational superiority of socialist society imposes. The processual character of the introduction of the principle of self-management into practice consists precisely of this, in the sense that it operates as a tendency of growth, starting of course from simpler forms and evolving toward the highest levels of efficiency and functionality, toward the forms specific to communist self-management.

CONTRIBUTIONS TO STUDY OF FUTURE GLOBAL PROBLEMS

Bucharest ERA SOCIALISTA in Romanian No 21, 5 Nov 80 pp 35-38, 52

[Article by Engineer Mihail Florescu]

[Excerpts] The Society of Waste

Research on a global model and limits of growth has continued. In 1976 the fourth Report to the Club of Rome was worked out with the title of "The Way Out of the Era of Waste." The report researched the problems in the three main areas: energy, raw materials and food production. The authors point out in the introduction that "science and technology are inestimable tools for confronting and solving the grave problems posed by the limited resources. At the same time, we must recognize that the current structure of the economic system does not permit a rapid solution to be made to some of the serious and urgent problems."[1]

Really, the current economic system cannot solve the crisis brought on by the difference between the rich and the poor countries, economic, financial and monetary crises which occur in rapid succession and which cause powerful economic imbalances with more serious consequences for the developing countries. Underdevelopment and undernourishment are deepening in a zone which comprises two-thirds of the world's population, while the oil and raw material crisis and the energy and fuel crisis have become chronic, breaking down the world's entire economic system.

In closing the report, which contains valuable economic analyses, the authors conclude: It is difficult to perfect a global policy and even more difficult for it to be accepted. Thus, we conclude by reasserting that the real limits of growth are more political, social and administrative than scientific and technological."[2] With this, the report leaves open the basic problem: the need to put an end to the consumer society, a society rightfully felt to be a "society of waste," a name which expresses more flexibly and more objectively one of the characteristics of modern capitalism.

An analysis of the models worked out until 1974 was made by Sam Cole of the University of Sussex, England. In the conclusions to his work, Sam Cole asks: "In which

1. Dennis Gabor and Umberto Colombo, "Sortir de [word illegible] du Gaspillage," Dunod Publishers, Paris, 1978, p 4.

2. Ibidem, p 226.

direction is mankind heading?" and he himself answers: "Any conclusion about global models for the long-term future will depend on the way in which the modeling is carried out further."[1]

Romanian Contributions To Working Out a Global Model

Romanian men of science have participated actively in the discussions and works which have enriched forecasting research in recent years. Romanian science has a critical and scientific attitude toward the models worked out and our country's researchers participate directly in international discussions, bringing their own viewpoints and valuable contribution to modern thinking about man's current and future development.

Mircea Malita has made an important contribution; besides the critical presentation of the models of the Club of Rome, he has set forth the scientific bases for working out a global model. In a valuable article published in VIATA ROMANEASCA in December 1974, he wrote: "A model is a mental or written qualitative or mathematical representation of a portion of reality which constitutes a system (that is, a whole, also having interconnecting parts). The model selects the most representative components of the system and describes the relations linking it. The creation of a model does not serve only knowledge but it also has practical goals. The model serves as a base for experimentation: We change a variable and look at the effects on the entire system."[2]

In order to work out such a global, objective and scientific model for the world economic system under today's historical conditions, when many economic systems exist and within them there are clear differences for each system separately from one country to another, it is practically impossible to achieve a global model for the world economy. Merely a global model for the economic relations among countries can be worked out, as it is conceived of under conditions of a new international economic order. This trend also is found in the recent models of the Club of Rome and, in particular, the global models worked out under United Nations sponsorship.

In the article mentioned, Mircea Malita poses a problem of great scientific integrity which deserves to be noted and remembered. "Someone may express his fear that together with Meadows' model the idea of the model will also be thrown out. Really, the scientific bo ness of creating global models must be retained. The attempt is fully justifiable if we take into account that we cannot dispense with the global models manufactured in our minds. We can find only a small number of factors in them."[3]

A global model can represent scientifically a unified system or relations which must be established among systems.

---

1. Sam Cole, "Global Models and the International Economic Order," Pergamon Press, 1977, p 74.

2. Mircea Malita, "Global Models" in VIATA ROMANEASCA No 12, December 1974, p 41.

3. Ibidem, p 44.

The differences between countries are clear, even in a unified social-economic system, so that in working out a model a very restricted number of general factors, which would be valid for the entire system, must be taken into consideration in working out a model. It is urgently necessary for the model world to work out a global model for the new international order, which would be a code for equitable and peaceful relations among countries, large or small, developed or developing.

"The trend of scientific concern in our times, which generically comes under the name of global models," Mircea Malita showed in the article quoted, may, through the quality of the work, sincerity of intention and efficienty of calculation, aid the effort to qualify the big options and to define a new world order, both in the economic as well as social area, to which it is inseparably linked."[1]

A broad critical and scientific analysis was achieved by Pavel Apostol in his work entitled "The Future," which appeared in 1977. The work proceeds from the methods for studying the future and, logically, it analyzes in a broad way the global models referring to man's future. In the preface the author notes: "With this conceptual and methodological apparatus I have attacked the problem of "global models," in this regard, too, stating new directions for improving them from a viewpoint which I have made valid and in direct or written confrontation with the authors of some of these constructions regarding human problems."[2] The natural and social sciences, mathematics and information systems, logic and dialectics contribute to the same extent to working out models for man's future. Thus, it is a scientific mission of very great dimension.

Making critical inroads in models of the world, Pavel Apostol scientifically characterizes Meadows' work in this way: "The limits of growth signaled the irrational nature of economic growth in the very industrially advanced capitalist countries and have shown that it creates insoluble problems if the very principles of the particular economic system are not questioned, and the contradictions caused in several capitalist countries by this growth, on the basis of economic interdependencies, can bring a break in the world balance in the foreseeable future."[3] Proceeding from this broad analysis, Pavel Apostol presents some of the most important critical conclusions, from which I repeat the following: Global models are clearly simplifications and approximations of a possible or really original(here we have the future of the world); models, as we know, are aggregates of variables obtained through disintegration of the original; the disintegration of the "world" quasisystem has been achieved and is being achieved according to heterogenous criteria (even within one and the same model), although all the decisions associated with the model or included in decisionmaking models are political, current models make an abstraction of relations of force at the national, "regional" and international level and of their probable evolution and as such—like it or not--create the dangerous illusion that the future depends only on decisions regarding techaical rationality, the models of the world quasisystem do not conceive of this or of its partial systems as learnable systems (through their program, experience, through scientific information and so forth).[4]

2. Pavel Apostol, "The Future," Scientific and Encyclopaedic Publishers,1977, pp 10-11.

3. Ibidem, p 221.

4. Ibidem, pp 246-269.

Formulation of these critical elements of models of the world, as worked out in the developed capitalist countries, is accompanied in the work published by Pavel Apostol by an presentation of the dialectical methods for studying the future, on which base the global models of the world are to be worked out. The studies of methodology in these areas are more and more numerous and will permit multidisciplinary and interdisciplinary paths to be chosen for working out models on which base the social-economic organization of the world can be deciphered in the near future and further in the future.

Under sponsorship of the Central Institute of Economic Research and Institute of Socialist Economics, the work entitled "World Economy: The Horizon of 2000,"[1] which groups a number of economic studies, going from the general problems of the world economy up to development of the main economic branches, was published. The studies presented are of a forecasting nature and attempt to determine what the main directions of development will be up to the end of the century.

The problems of forecasting development by short or long-range periods have generated the interest of men of science, governments of all countries as well as international organizations, particularly the UN.

Single-Subject Models

Along with the works which treat the global model of the world, it has been felt useful to publish some studies whose subject was an analysis of a single subject, which permitted a deepening and broadening of the vast problems of the global model of the world.

In this framework, the forecasting collectives of the Academy of the Socialist Republic of Romania organized broad discussions, which were published in the series entitled "Man's Global Problems." In the preface to the first work published, Mircea Malita, coordinator of the series, points out that the developed subjects are agriculture and nourishment, solar energy, electronics and information systems, resources of the seas and oceans, human settlements and systematization of territory, with discussions to be organized on the subjects of materials and chemistry, science and technology, intra-atmospheric space, biology as well as human resources.

Publication of the first works stirred the interest of specialists and the public at large. The work entited "Energy in the Next Three Decades" was written under the leadership of Dr Engineer Calin Mihaileanu, director of the Institute for Research and Energy Modernization. In the preface, Mircea Malita points out what the role will be of publishing many chapters in each work as approached by a large number of scientists and specialists: "By definition, the decision is a choice between more than one alternative but, in order for them to be able to be weighed and the good strategies of development to be worked out, any version and any option must be presented with all its implications."[2]

1. Coordinators: Mihail Florescu, Mircea Malita and Marcel Horowitz.

2. "Energy in the Next Three Decades," Publishers of the Academy of the Socialist Republic of Romania, 1979, p 8.

Stressing the need to work out a strategy for providing the energy base for the country's economic development in the long range, Dr Calin Mihaileanu, at the same time, points out that "together with the stress on the interdependence between nations, it is becoming more and more clear that national energy policies must be based on experience and knowledge of a horizon at the world level and for the long range, with which the national programs should be coherent and compatible."[1]

The 12th party congress approved such a national model through the Program Directive for Development of Energy Resources for the 1990-2000 Period, establishing the directions which will assure the energy base for our country's entire development.

In the work entitled "The Future of Electronics and Information Systems," coordinated by Prof Mihail Draganescu, the main problems resulting from the revolution of information systems and its implications for the entire development of society are treated. The revolution in information systems was possible due to the electronic revolution and, more recently, microelectronics, which caused radical changes in the automatic management of production processes and in automatic data processing, basic aspects which must be taken into account in the strategy of development and in working out models by branches or global models.

The appearance of the work entitled "Nourishment and Agriculture in the Next Three Decades," coordinated by Academician Nicolae Giosan, has great importance in knowing the problem and working out solutions to eliminate undernourishment for one-third of the world's population. The discoveries in biology are becoming an important component of the scientific-technical revolution not only in the process of knowledge; broad opportunities are opened for providing nourishment through the rapid development of biochemistry and bioengineering and by moving to the broad-scale use of enzymatic processes and microorganisms, while current agricultural techniques and practices will be revolutionized due to genetic engineering.

In one of the studies in the work, Academician Nicolae Giosan stresses that "food production is being confronted more and more not only with the energy crisis but also with the entire series of problems of economic growth and elimination of the differences between levels of development of various regions and countries. Failure to resolve the problems of nourishment as one of the basic problems of human existence can have serious implications for thecourse of world evolution."[2]

For these reasons, all the global models worked out approach the problem of nourishment as one without which human civilization cannot be thought of.

We await the continuing publication of the works announced, with the wish that they represent an important contribution of science in our country to clarifying the global problems of mankind and to working out models with a solid sc entific base and real solutions.

SLOVENIAN EMPLOYMENT PLANS TO 1985

Belgrade PRIVREDNI PREGLED in Serbo-Croatian 6 Nov 80 p 8

[Article by Ljubomir Krasojevic: "Slower Growth in the Future"]

[Text] The growth rate of employment in the coming medium-term plan in Slovenia is brought into closer relationship with the tighter conditions for economic activity and stabilization trends, which require optimum employment of manpower and thereby a faster growth of income per employee. The draft of the social development plan of Slovenia up to the year 1985 provided that employment in the economy and social services would increase considerably slower than up to now.

That is, as set forth in that document, the economic capabilities allow employment to increase at an average annual rate of 2 percent in associated labor over the coming 5 years. Of that employment in the economy would increase at a rate of 1.8 percent and employment in the social services about 2.2 percent and employment in public organizations and communities a maximum of 1.9 percent annually. The growth rate of employment in the less developed regions would be slightly higher, and in the more advanced regions it would be below this republic average.

On the basis of these predictions it is assumed that in the coming period new jobs could be opened in the republic for 80,000 workers, one-fifth of them in noneconomic activities, above all in the social services. There are also realistic prospects for opening up another 7,000 new jobs in the self-employment sector. Toward the end of the next medium-term period, it is being planned, there would be a total of 880,000 persons employed in associated labor and self-employed in Slovenia. That would keep the share of the work force in the total population at the same level of about 45 percent.

Obligations of Associated Labor

The conceptions of development state that advantage in hiring must be given in coming years to young trained personnel. However, it is well known even now that difficulties will arise because of the discrepancies between the

training of the new personnel coming from the schools and the particular occupations which associated labor really needs. In the first years of the medium-term plan the share of unemployment in the republic, it is now estimated, will range between 2.5 and 3 percent.

Though the republic's medium-term development plan foresees a considerably slower growth of employment than has been the case up to now, it is felt that even the low rates foreseen impose substantial obligations on associated labor. That is, the self-management accords signed by all the opstinas in the republic commit organizations of associated labor to make provision for total social costs of every new job so as to ensure what is called the minimum standard of living and working conditions.

Moreover, the restructuring of the economy, which is one of the republic's strategic lines of development, necessitates a higher level of knowledge and professional competence on the part of workers, and thereby an increased share of the appropriate skills in the total work force. The changes envisaged in the pattern of work, the introduction of automation into production processes, and then the better organization of work and reduction of the share of office and staff personnel, will necessitate effective resolution of the problems of manpower surpluses in a considerable number of organizations of associated labor. These work organizations, and it is believed that their number is not small, will have to be prepared even now for timely adoption of programs to equip and train personnel for new specialized knowledge, which would be accomplished in collaboration with opstina employment security communities.

Maximum optimality in hiring is becoming one of the essential prerequisites in Slovenia for stabilization, for more efficient conduct of economic activity, and thereby for the rise of labor productivity. The growth rate of employment in the current medium-term period has been considerably above the projection. That is, the most recent studies show that only in the first year of the current medium-term plan, 1976, did the growth rate of employment in Slovenia remain within the limits of the projection, when it showed a growth of 2.9 percent. The very next year the growth of employment was 3.1 percent, in 1978 it was 4.1 percent, and last year that percentage dropped to 3.3. On that basis it has been calculated that employment in the current medium-term plan has so far shown an average annual growth of 3.5 percent.

Productivity Below the Projection

It is true, and current analyses so demonstrate, that the growth rate of employment has been considerably more modest since the end of last year and up to the present time because of the effect of the stabilization measures which were adopted. Though the slower growth rate of employment is typical of all organizations of associated labor in the economy, so that by all appearances the growth this year will be about 0.5 percent, it has been especially marked in organizations of associated labor in physical production,

which account for 57.3 percent of the workers in the economy. That is, in this domain of associated labor the number of employees has hardly changed at all since last December.

Though the stabilization measures will undoubtedly tend to bring the markedly dynamic growth rate of employment over the past 4 years into the somewhat more realistic limits of the original predictions by virtue of the results expected in 1980, this is one of a number of reasons for the slower rise of productivity in this republic.

The following comparative figures best illustrate the kind of growth of productivity we are talking about. The most recent analyses of progress in fulfilling the current medium-term plan show that the share of the rise of productivity in the growth of total output of associated labor has been 42 percent over the past 4 years, which is 15 percent less than was planned. In the industrial sector, however, the contribution of the rise of productivity to the total growth of output was 63 percent, or 3 percent less than was envisaged. If the estimates which have been made are borne out this year in the context of the quite appreciable moderation of the growth of output, productivity could increase as much as 2 percent. Then its share in the growth of the social product would be 50 percent, which is still 7 percent less than was planned.

PRIVATE SECTOR CRUCIAL TO FOOD PRODUCTION

Belgrade PRIVREDNI PREGLED in Serbo-Croatian 6 Nov 80 p 4

[Article by Tomislav Kapetanic: "The Private Farmer (Un)reliable as a Partner"]

[Text] Deagrarianization in Yugoslavia means above all the abandonment of agriculture as a principal occupation. Under the altered conditions it is becoming a secondary or supplemental occupation based on retained ownership of land. Deagrarianization has not been followed at the same time by deruralization. It is this fact that is continuously renewing the urgency of the question of the possible level and manner of production to meet society's ever greater needs. This kind of peasant, or more precisely half-peasant, is objectively an unreliable partner as a commodity producer of food, since at best he realizes only a third of his total income from farming, but obtains the major portion by working at other jobs.

The total number of private farms has held at 600,000 for quite a lengthy period now. Some, it is true, disappear, but new ones, most of them tiny, are also springing up through inheritance and division, through purchase and similar ways. The small size of landholdings, their dispersion and the fact that they consist of tiny detached pieces (in Croatia there are even now 18 million cadastre parcels) objectively hampers the more extensive and effective use of machinery and the pooling of labor and capital with the socialized sector of agricultural production. These are the limiting factors in private agriculture, where there are fewer and fewer "pure" farmers. Let us add to that the datum that in Croatia at the present time, aside from the 600,000 farmers, there are also another 300,000 persons, persons who are not engaged in agriculture, paying taxes on the basis of possession of land. Certainly this trend is not contributing to the needs for a major growth of agricultural production.

It is evident from this brief sketch of our "peasant question" that the present structure of agricultural production is by virtue of many of its characteristics and tendencies holding back the development of up-to-date production, but at the same time in many of its tendencies and manifestations it leaves room for action and for faster progress in a more extensive

process of socialization and development of socioeconomic relations. Up to now, however, the adverse aspects have manifested themselves more markedly. The new law on farmland, which was prepared last year and has already been thoroughly debated, takes the agrarian structure of this republic into account. It therefore contains solutions which could considerably mitigate the adverse tendencies and make it possible to implement the general principle that the land is a resource of general importance, with all the consequences which follow from that principle.

It is unrealistic to expect, however, that the law alone, without the broadest social campaign, can guide the very problematical movements and processes in this sensitive field of food production. It is obvious that the private sector of agriculture, with its tendencies and contradictions, has not yet reached the center of public attention and study with a view toward its guidance and planned inclusion in the lines of society's development. There is no doubt that this is the portion of our economy which is developing most spontaneously and to the greatest extent without an appropriate program.

Paper Cooperatives

When we speak about "aggressive programs" in food production it is natural that reliance should be put first of all on public farms and socially organized production, which must not bypass the present. In many places, however, the private farmer is left to himself and has no basic link to the socialized sector of agriculture, and often he has lost even his cooperative, which was the only point of support and collaborator in a production which would ensure satisfaction of broader needs.

In the country as a whole about 400 agricultural cooperatives have disappeared over the last 4 years, and their property has been taken over by agricultural combines and institutions in the distribution sector. The paradox is that a considerable number of the cooperatives went out of existence in the period when the flood tide of farmers joining cooperatives, basic organizations of cooperators and other forms of association would occur. What occurred was a low tide with immeasurable consequences. Regardless of its rapid development trend, the public sector is a weakling when it comes to producing food when one compares its capacities with the capabilities of the private sector. The crop planting plan in Croatia for the 1980-1981 farming year, for example, assumed 405,000 hectares of peasant plowland would be planted to corn (the socialized sector's share is only 85,000 hectares). Private farmers will grow potatoes on 82,000 hectares and the socialized farms on 200 hectares. These are just two figures which even alone are sufficiently eloquent.

But what could be done by the economically disorganized peasant who has been left to the haphazard play of the market and to partners who are looking mostly to their own interest? The reasons for the present situation are many, ranging from the one-sidedness, half-heartedness, formalism and

inconsistency in applying the principle of self-management to the organization of farmers' associations, to the inherited conception of the farmer as a kind of private entrepreneur, one which in the past led to a drastic neglect of his rights to self-management, one of which is the right to form associations.

Certain cooperative organizations in Croatia have understood that they could not operate by earning income on the purchase-sale conception of relations with rural areas, and they developed authentic relations based on shared income. Business books are kept for each private farm in the area they serve, and they jointly plan and provide for the conditions of production and adopt production and sales strategies.

The End of Planning Done Behind Closed Doors

It is particularly important to carrying out a more extensive program of food production in socially organized production in the private sector that the formation of farmers' associations assume more massive proportions and attain a higher quality. Many of the present number of associated farmers in Croatia (38,672), farmers involved in lasting forms of cooperation (184,930) and those who occasionally collaborate with cooperative and other organizations of associated labor (109,201) will probably move into higher categories in the coming period, since they are counted on as significant producers of food, and it is expected that toward the end of 1985 this republic would have about 50,000 specialized commodity producers (for milk, meat, vegetables, fruit and grain). Since today there are only 15,000 of them, this increase would signify a new qualitative attribute not only for planning, but also for the total volume of production of products for the market.

The socialized sector of agriculture, which in 1979 had a share of 19.5 percent in total arable land and 45.3 percent in total production of the most important field crops (wheat, corn and sugar beets) as well as 34 percent in total meat production, has been expanding slowly for quite a long time now--as compared to the rate of growth of the needs of centers of consumption and export, and socially organized production cannot make up for the consequences of deagrarianization to the necessary extent. The length of the new leap in production will probably depend mostly on the size of funds invested in socialized production and on this sector's organizational capability to tie private farmers more firmly to its plans for food production in the new planning period up to 1985.

Cheap Solutions Are Not the Best

This commitment has also been made imperative by the fact that the agroindustrial complex has become a more significant factor in the stabilization and coordinated development of the entire economy than it was in the past and by the fact that it will be so in the future to a greater and more decisive extent as the material and social linkage and also interdependence

between that complex and the rest of the economy necessarily becomes greater and greater during future economic development. Cheap solutions such as importing food when domestic resources fall short are not socially justified. Actually they did not fall short in fulfilling the production program, since the output was larger. Nevertheless, in spite of all that, though it sounds paradoxical, the overall development of food production, which on the whole was favorable, did not keep up with the exceptionally large and steadily growing needs of society.

It is also obvious that total demand considerably exceeded the planning predictions. We are examining in the overall context all the implications of the profound changes in the socioeconomic composition of the population for the production and consumption of agricultural products. The advanced process of deagrarianization has reduced the farm population to 20 percent of the total population. At the same time the growth of the farm income from farming and especially the nonfarm income of the farm population—and indeed the income of the rest of the population—has enormously increased the consumption of finished farm products and processed foods and in a relatively short time has increased the pressure on society's food stocks many times over.

In the overall view primary production, with its average annual growth rate of 3.8 percent and tendency to slow down, is not keeping up with demand. In future it must therefore have a considerably faster and more stable growth trend. In the coming medium-term period conditions for production are being essentially improved on 220,000 hectares of arable land in the private sector, and the basis is being created thereby to set up a portion of the private farmers as producers for the market thanks to association and higher income. The area to be planted in the socialized sector is also increasing by 110,000 hectares through various forms (between 70,000 and 80,000 hectares of grain, 10,000 grains of sugar beets, 20,000 hectares of livestock feed and vegetable crops, and 6,000 hectares of large new fruit and grape plantings).

Physical production in the period 1981-1985 ensures among other things about 5 million tons of grain, nearly 2 million tons of sugar beets, 1.9 million tons of vegetables, 154,000 tons of oilseed, 368,000 tons of meat and 1,180 million liters of milk. The plan for development of primary production is much more ambitious than previous first projections, especially in comparison to the fulfillment of previous plans in Croatian agriculture.

PARTY OFFICIAL CALLS FOR BETTER MANAGEMENT OF ECONOMY

Sofia IKONOMICHESKI ZHIVOT in Bulgarian 29 Oct 80 pp 1, 6-7

[Interview with Krustyu Trichkov, candidate member of the BCP Central Committee Politburo, deputy chairman of the Council of Ministers and chairman of the Committee for State and People's Control: "For Active and Aggressive Control Activities"]

> [Text] The forthcoming 12th Party Congress is an important event in the life of the party, the people, and the country. On this occasion Comrade Krustyu Trichkov was asked by the editors some questions related to the work of the control organs and economic cadres in the period preceding the 12th BCP Congress.

Question: Comrade Trichkov, how do you assess the role of the forthcoming highest party forum in terms of the further development of our economy?

Answer: Each party congress is a new step in the building of a developed socialist society in our country. Unquestionably, the 12th Party Congress will play an exceptionally important role in the development of our socialist economy. Comrade Todor Zhivkov himself has emphasized that, "It would be no exaggeration to say that the 12th Congress will mark a period of deep quality changes in the development of the Bulgarian socialist economy."

First, the congress will supply a decisive impetus to the practical implementation of our course for high effectiveness and quality.

Second, ripe and major problems of our development will be formulated and resolved, such as the systematic application of the new economic approach and new economic mechanism in the organization and management of the national economy, and a decisive upgrading of social labor productivity; the rapid and energetic application of the highest modern achievements of the scientific and technical revolution and of global experience; and raising agriculture to a new level of development.

It is on this solid foundation that the 12th Congress will confirm the party's course of further enhancement of the living standard of the people and the ever fuller satisfaction of their material and spiritual needs. The congress will earmark important practical measures for the implementation of the December

party program, particularly in the production of more consumer goods, trade improvements, self-satisfaction of settlement systems, and others.

Question: Recently the July BCP Central Committee Plenum reviewed the implementation of the basic indicators of the Seventh Five-Year Plan in the economic and social policy areas. What are the positive and negative sides of this balance?

Answer: The results achieved by our people under the party's guidance in the Seventh Five-Year Plan indicate that a new major forward step was taken in the socioeconomic development of the country. Thanks to the selfless work of all working people in our country a stable rate of increase of the national income and of the overall development of the country was achieved. This was accomplished despite the rather complex circumstances created by the energy-raw material and monetary crisis of capitalism.

The results achieved in the Seventh Five-Year Plan make us legitimately proud not only of our economic accomplishments, which created a solid foundation for the further implementation of the December program for upgrading the living standard of the people, but in the areas of foreign economic relations, stabilization of our foreign exchange balances, and others.

At the same time, dissatisfaction with current results and with new creative searches was expressed at the July plenum. It was pointed out that these achievements did not constitute the limit of our economy and our socialist economic system, and that the possibilities were far greater. We must acknowledge that in virtually all national economic sectors the contradiction between the possibilities of the developed material and technical base, tremendous in terms of our scale, and its insufficiently efficient utilization by the subjective factor, determined at the 11th Congress and analyzed at the July 1976 BCP Central Committee Plenum, has not been surmounted yet.

The problem is easy to understand. We still have a number of economic units whose managements allow in their work substantial weaknesses of a most different nature: unjustified idling of machines and equipment, poor organization of the work, violations of technological and labor discipline, and many other reasons, all of them subjective. This situation is intolerable and, naturally, being conscientious creative workers, we cannot tolerate it.

Question: On what aspects of the nationwide pre-congress competition should we focus our greatest attention?

Answer: The 12th Party Congress will offer broad scope for the initiative and energy of the party organizations, party members, cadres, public, economic and cultural organizations, and working people in their competition which is already covering all areas of material production and all activities in the country.

Comrade Todor Zhivkov pointed out two particularly important aspects of this pre-congress competition:

First, the struggle for the fulfillment and overfulfillment of the 1980 counterplan. Those who resolve this problem most successfully will welcome the congress in the best possible and most worthy manner.

Second, on this basis, insure the ever fuller satisfaction of the material and spiritual needs of the common people, of all working people. Concern for man will remain the basis of the party's policy and the most immediate concern of party, state and economic managements. We must decisively implement the tasks we have set ourselves.

Something else which was particularly emphasized by Comrade Todor Zhivkov is that in the struggle for properly welcoming the congress, "Action is the main thing! Not noise but action, not big words but specific practical results! Actions, actions and actions again!"

The reason I am voicing these considerations in particular is because they are profoundly meaningful and fully apply to all economic cadres.

Question: Comrade Trichkov, it is common knowledge that one of the factors for the successful functioning of the entire economic mechanism and the implementation of the plans is control, socialist control in particular. What is the place assigned to the control system in the preparations for worthily welcoming the 12th Party Congress?

Answer: The organs in charge of overall socialist control are among the most typical traits of the democratic nature of our society. They are the offspring of socialism and the attribute of the socialist state. The state and people's control organs are one of the effective means for exercising daily control over all aspects of the work of state and economic organs, enterprises and organizations by workers, peasants, and the intelligentsia, and of their right to do so. Over 220,000 people's controllers, members of public organizations, men of science and culture, workers, peasants, and employees are working on a voluntary basis within the effective system of the state-public organization of state and people's control organs.

The people's control commissions and groups have become the basic mass support of the state and people's control organs.

The people's controllers are fighting violations with an unerring inner sense of justice. The activities of the people's control commissions are so comprehensive that they have grown into a self-control system, into an individual and mass self-imposed obligation. Their comprehensive activities which are currently particularly actively manifested in the pre-congress competition are an expression of experience directly based on reality. It proves the inexhaustible possibility of the people's masses to be creative even in an area such as control. That is why the dedicated work of the people's controllers is deservedly highly rated by our party. Ninety-four active and properly working people's control commissions in economic organizations, large enterprises, and establishments were reorganized into state and people's control committees based on production activities. This considerably broadened the right of control and of holding accountable control organs immediately responsible for the work of labor collectives.

Naturally, this alone does not cover the entire democratic and voluntary principle of control work. The close interaction between the Committee for State

and People's Control and the people's controllers, on the one hand, and the public organizations, the Fatherland Front, the Bulgarian Trade Unions, the Komsomol, the women's councils, and others, on the other, is a powerful factor in the manifestation of the broadly democratic principle governing control activities.

Question: Comrade Trichkov, the Law on State and People's Control offers real possibilities for the exercise of the citizens' right to control the work of the state apparatus and the socialist organizations. How are such opportunities used?

Answer: Let me clearly state that not all possibilities are used. For example, the law grants substantial rights to the people's control commissions to check, suggest to and demand of the administrative and economic managers to explain to the collectives the specific measures they have taken to eliminate some shortcomings and weaknesses. This is not implemented always and everywhere. The role of the people's control commissions has been lowered in some ministries and economic organizations. Far from everything possible has been done to make use of the potential of this mass support of people's control and to enhance the role and prestige of such commissions.

The Law on Suggestions, Reports, Complaints, and Petitions submitted by the working people was passed also for purposes of improving and democratizing social management. It assigns tasks to all control organs and all departments. The implementation of this law must be considered a legal act of great political importance. According to the law all work related to suggestions, reports, complaints and petitions to be the direct responsibility of ministers and managers. This is properly understood in many places. However, in a number of areas this is not being understood and this work is assigned mainly to the heads of the respective services. Work with letters sent by citizens is still being underestimated.

Another basic stipulation of the law is violated as well according to which all managers must set aside specific receiving days and hours. We are pained to admit that some managers find no time to see citizens and settle their problems.

We believe that the Committee for state and people's control and the other control organs are still not making use of their great potential for improving the state apparatus and its work--for reducing its size, eliminating callousness, bureaucracy and formalism, and improving work style and methods.

Today, in the active pre-congress efforts of all working people in our country, the control organs must find their proper place and role in the struggle against bureaucracy, formalism and callousness. We must not forget that the July 1980 Party Committee Plenum pointed out once again that we must openly confront the carriers of such phenomena and the violators of state discipline regardless of rank and position.

We have always ascribed great importance to the educational function of control based on the understanding that the main aspect of control is not to punish but

to play an educational and preventive role. Today, in the stage of building a developed socialist society, this becomes even more necessary. In this spirit I believe that with a view to intensifying the educational functions of control the results of each investigation and of established violations must be made available to the corresponding collectives. Weaknesses and their carriers must be exposed promptly. On the other hand, all the opportunities offered by the public organizations and mass information media extensively to publicize investigation results must be used. Publicity could greatly enhance the preventive aspect of control. In this spirit the leadership of the Committee for State and People's Control highly values the role and significance of the joint initiative sponsored by the committee and by IKONOMICHESKI ZHIVOT of publishing materials under the heading of "Under the Control of the People."

Nothing undermines the foundations of what is base and immoral better than their public exposure and shaming. Frequently a violation, a crime is committed behind the people, stealthily, secretly. Publicity exposes it to the light. It becomes known by the masses, public intolerance develops, and a moral educational reaction is triggered. That is why an investigation and its results must be made public at all levels in posters, exhibits, displays, letters, wall newspapers, pamphlets, flash announcements, enterprise newspapers and radio broadcasts, and the local and central press. The violators must be publicly exposed at every step. This will greatly contribute to the enhancement of moral norms and to better behavior. It would enable us to eliminate negative features such as lies, thefts, egotism, greed, consumerism, gross selfishness, and careerism. In the final account, these are the sources of actions with adverse consequences in terms of public property.

Finally, allow me through IKONOMICHESKI ZHIVOT to mention some of the most topical problems which are being resolved by the control system now, in the period preceding the 12th Party Congress. Above all, the state and people's control organs and the entire control system must focus their efforts and attention on the implementation of the 1980 counterplan in all sectors, for all quality indicators, and in physical terms. In this area we will continue to pay particular attention to the timely harvesting and most efficient utilization of agricultural commodities.

Another exceptionally important problem requiring investigation is that of the proper utilization of raw materials, materials, energy and fuels, manpower resources, and equipment. This mass investigation would enable us to hold accountable anyone who has adopted a formalistic attitude toward this problem of exceptional importance to our economy and development.

The task set by the July plenum of producing additional consumer goods worth 550 million leva, whose implementation is being investigated, is very important from the economic viewpoint.

Major problems must be resolved in the field of transportation with a view to the development of a most efficient organization for the utilization of the rail, road, and water transport systems.

In the field of construction an extensive investigation must be made on the accelerated commissioning of productive capital planned for the Seventh Five-Year Plan and reduce the volume of unfinished construction by 20 percent.

The investigation underway, involving the entire control system, of the application of new technologies and of the requirements of the new economic approach in the formulation of the 1981-1982 plan for the socioeconomic development of the country--years within the new five-year plan, the five-year plan of technical progress, production intellectualization, and comprehensive and full application of the new economic approach, a five-year plan of sharply increasing labor productivity and raising the living standards of the Bulgarian people--is of exceptional importance.

As you may see, those are merely some of the major and responsible tasks facing the control system. Unquestionably, more than at any other time, today we need a militant, an aggressive control activity and an open confrontation with all violators of discipline and all manifestations of disorganization and slackness, regardless of their origin or their agents.

As always, the control organs today are responding to the party's call for worthily welcoming the 12th BCP Congress. Unquestionably, they will remain in the leading ranks of the struggle for its worthy welcoming, in the struggle for building developed socialism in our country--the Bulgarian People's Republic.

ORDINANCE REGULATES CUSTOMS INSPECTIONS, DUTIES ON PARCELS

Sofia DURZHAVEN VESTNIK in Bulgarian 17 Oct 80 pp 997-1007

[Ministry of Finance Ordinance No 5 on customs control of international parcels]

[Text] Chapter 1

General Stipulations

Article 1. (1) The present ordinance regulates customs control of mail parcels sent abroad or received from foreign countries by local residents and foreigners residing in our country with the exception of the ones stipulated in the following paragraph.

(2) Customs control of parcels received or sent by foreigners enjoying diplomatic immunity on the territory of the Bulgarian People's Republic shall be based on the stipulations of the Ordinance On Customs Handling of Baggages and Parcels Imported or Exported by Foreign Missions and Their Personnel (DV, No 71, 1970; amended, No 58, 1971 and No 69, 1978).

(3) Parcels containing mail alone shall not be subjected to customs control.

Article 2. (1) The postal administration shall deliver to the addressees parcels received from abroad and shall accept parcels to foreign countries only by permission of the customs office, insuring the necessary conditions for customs control.

(2) The permission of the customs office shall not be required in the case of mail correspondence and whenever the postal administration has been assigned by the minister of finance to perform customs duties with the agreement of the minister of communications.

(3) All activities related to the handling, transportation and storage of international mail parcels shall be carried out by the postal administration in accordance with Ordinance No 4 on postal communications (NPS) (DV No 97, 1979), and in accordance with the present ordinance.

(4) Postal employees shall open the parcels under the supervision of customs officials and submit for checking by customs of the objects they contain. They shall measure, count and replace the objects in the parcels.

Article 3. (1) Customs control of international parcels shall be provided by the customs offices in the country in their individual areas (Appendix No 1) through a customs investigation of the content of the parcel and control of the documents accompanying it.

(2) Customs officials shall set the customs fees for international parcels unless such activities have been assigned to postal workers as per the Regulation On the Application of the Law on Customs (PPZM) (DV, No 12, 1975; amended and supplemented, No 49, 1978).

An official document shall be drawn up in accordance with the stipulations of the NPS in the following cases: discrepancy between the objects included in the international parcel and their description in the customs declaration; a parcel not accompanied by a customs declaration; damaged wrapping; or spoiled or damaged objects in the parcel.

(4) Should it be determined that the parcel contains objects whose import or export is forbidden and which are not listed in the accompanying documents, or else that the parcel contains objects placed in such a way as to avoid customs control, a document is drawn in accordance with the stipulation of the Law on Customs (ZM).

Article 4. (1) Objects for individual or family use may be sent or received with international parcels in accordance with the stipulations of the ZM, the PPZM and the present ordinance, and in accordance with the requirements of the border veterinary-sanitary and phytosanitary control.

(2) The export or import from and to the Bulgarian People's Republic of items listed in Section I of Appendix No 2 is prohibited.

(3) Items listed in Section II, Appendix No 2, may not be exported duty-free with the exception of the stipulated cases.

(4) The systematic sending and receiving of international postal parcels by the same individual is prohibited. Receiving (sending) more than one parcel quarterly shall be considered systematic.

Article 5. (1) The stipulations of the NPS and the Universal Postal Convention shall be observed in terms of the type, packaging, size, weight, addressing and franking of international postal parcels.

(2) The postal administration shall bear material responsibility for the loss, theft or damaging of international postal parcels in accordance with the cases and stipulations of the NPS.

Chapter 2

Customs Control and Fees Levied on International Postal Parcels

Section I

Importation

Article 6. (1) International postal parcels arriving from abroad to border exchange points shall be sent to the exchange postal station of the Sofia customs office with a transportation sheet issued at the border customs office on the basis of a description drawn up by the postal service.

(2) The transportation sheet shall be drawn up in two copies. One copy shall be kept by the customs office while the second shall accompany the parcel to the exchange postal station of the receiving customs office which shall initial it and return it to the issuing customs office.

Article 7. (1) The exchange postal station at the Sofia customs office shall distribute the international postal parcels for the levying of customs fees among the customs offices of the rayons listed in Appendix No 1 and ship them to the corresponding post offices of the settlements where such customs offices are located.

(2) Customs control over small parcels bearing a rhombic-shaped seal on the packaging, arriving from countries signatories of the 30 May 1963 protocol on one-sided customs control of small packages (GDR, Poland, USSR, Hungary, Czechoslovakia) shall be provided by the Sofia customs office of the Sofia Central Post Office, after which they shall be sent directly to the post offices of their destination to be delivered to the addressees in accordance with the NPS.

(3) Small packages with a rombic seal are not subject to customs control. The customs office may control such parcels for sanitary, veterinary, or other non-customs security control reasons or should small parcels be systematically received by the same individual.

Article 8. (1) The postal services shall submit to customs offices arrived international postal parcels with a description of the contents in two copies in accordance with NPS procedures, together with shipping receipts and customs declarations accompanying the parcels.

(1) One copy of the description shall be kept by the customs office while the other with the shipping receipts and customs declarations shall be returned to the postal service.

Article 9. (1) In the case of international parcels containing items subject to custom fees the following documents shall be issued in duplicate: import receipt, when the fee is collected by the customs office, or a postal customs duty document, when it is collected by the post office.

(2) The receipts (post office documents) shall contain a description of the items by type, quantity and value; they shall indicate shipment stipulations and the duty to be charged.

(3) One copy of the import receipts or postal document shall be sent by the postal administration to the addressee who must appear and pay the customs fee either directly at the customs office should it be located in the same building as the exchange post office or at the post office in all remaining cases.

Article 10. (1) Should the international postal parcels contain duty-free items the shipment report must be processed by the customs office.

(2) Following the delivery of the parcels to the addressees the reports shall be submitted to the customs office for filing as customs documents.

Article 11. (1) The actions of customs officials related to the levying of customs fees on international postal parcels may be appealed to the head of the corresponding customs office prior to the delivery of the parcel to the addressee.

(2) The petition shall be presented directly to the customs office or through the post office where the parcel is located. The addressee shall be given the possibility to check the content and customs fees in the presence of a post office official. Should the complaint be filed at the post office, it should be sent, together with the parcel and the post office document to the customs office which levied the customs duty.

(3) The customs office chief shall appoint a review commission as per Article 81 of the PPZM, after which the parcel and the customs duty document on whose reverse side the results of the second review has been entered, shall be returned to the corresponding post office for collection of the duty owed and for delivery of the parcel to the addressee as per the NPS.

(4) Customs fees may be appealed to the Customs and Customs Control Directorate of the Ministry of Finance. The appeal must be submitted to the customs office no later than seven days following receipt of the announcement of the fee charged and before delivery of the parcel to the addressee.

Article 12. Undelivered international postal parcels shall be delivered to the customs offices as per Article 69 of the PPZM and treated in accordance with Articles 101 and 102 of the PPZM.

Section II

Exportation

Article 13. (1) Customs processing of international postal parcels shipped out of the country shall be carried out with customs declaration form S2/SR3 for mail parcels (Appendix No 3) or label S1 for small parcels (Appendix No 4).

(2) The declaration and the label must be filled by the senders, indicating precisely the type, quantity, and value of exported items on the basis of Bulgarian retail prices.

Article 14. (1) Citizens may send parcels abroad through all postal stations with an export permit which may be issued by: the chief of any customs office; the chief of any post office, should the value of the content be no more than 30 leva Bulgarian retail prices. In bigger customs offices or post offices an export permit may be issued by a specially assigned official.

(2) The permit shall be issued in writing: On customs declaration S2/SR3 for mail parcels; on label S1 and the wrapping for small parcels.

(3) Customs declaration form No S2/SR3 shall also include the number, date and amount of the collection order showing that export fees have been collected.

(4) The declaration shall be attached to the report on the shipment of the parcel and kept by the control office of the Sofia customs office.

Article 15. The wrapping of small parcels the value of whose content does not exceed 30 leva, shipped to countries signatories of the 30 May 1963 protocol on a one-sided customs check of small parcels shall mandatorily carry the rhombic seal stamped by the local customs office for small parcels accepted by post offices in settlements with a customs office or by the Soviet customs office for all small parcels accepted by post office settlements without a customs office.

Article 16. (1) Accepted parcels with their accompanying documents shall be shipped to the international exchange post office of the Soviet customs office as per NPS procedure.

(2) Customs control of international postal parcels accepted for export by post offices throughout the country shall be provided by the Sofia customs office which, in cases of doubt, shall recheck the content of the parcels.

(3) Postal parcels received by the Sofia customs office without a customs declaration or with an improperly filled customs declaration shall be returned to the initial post office for proper completion.

Article 17. International postal parcels shall be shipped to the border customs offices together with a customs sheet issued by the internal customs office on the basis of the description list drawn up by the exchange post office.

Section III

Transit

Article 18. (1) The transit shipment of international postal parcels across the territory of the Bulgarian People's Republic shall be allowed providing that the parcels do not contain objects prohibited by the Universal Postal Convention or other international treaties or legal documents.

(2) International postal parcels containing objects whose import in the Bulgarian People's Republic is forbidden may be hauled in transit only by permission of the customs office chief.

Article 19. (1) Customs control of transit international postal parcels shall be based on documents.

(2) Bags with transit international postal parcels as well as the parcels themselves shall be passed by the customs offices entering or leaving the country without being opened and without the breaking of foreign seals.

(3) The following shall be subjected to customs control: In cases of justifiable doubt that the content does not correspond to the accompanying documents; should the packaging be damaged or should its appearance lead to the assumption that its content has been damaged.

(4) The opening of the bags or the parcels themselves as stipulated in the preceding paragraph shall be conducted jointly by customs and post office officials. The results of the investigation shall be entered in a document one copy of which shall remain in the customs office while the second shall be delivered to the postal service.

Article 20. (1) International postal parcels shall be accompanied by a transit sheet issued in duplicate by the customs office at the point of entry on the basis of international postal documents and the post office descriptions drawn up by the postal service.

(2) The customs office at the point of exit shall check the condition of the wrapping and the seals and number of bags. Should they correspond to the entries in the transit sheet, the bags shall be passed through customs. The customs office shall initial the transit sheet and return it to the customs office at the point of entry.

Chapter 3

Duty-Free Imports and Exports

Article 21. (1) No duty shall be levied on the following:

1. Parcels whose content is worth no more than 10 leva in Bulgarian retail prices, shipped to local or foreign physical persons;

2. Parcels arriving from socialist countries and addressed to local physical persons, providing that their content is not worth more than 30 leva, Bulgarian retail prices;

3. Small parcels bearing a rombic seal on the wrapping, arriving from countries signatories of the 30 May 1963 protocol on one-sided customs control of small parcels;

4. Parcels received quarterly by members of families of Bulgarian citizens residing abroad for purposes of work, specialization or assignment for over six months in accordance with the restrictions stipulated in Article 23 paragraph 1 of the present ordinance;

5. Parcels containing food products, clothing, shoes, and other objects for the personal needs of foreign students, graduate student, secondary school students, and others, attending Bulgarian educational institutions;

6. Parcels containing items for the personal and family requirements of foreign specialists working in Bulgarian institutions, enterprises or organizations;

7. Parcels containing local goods regularly shipped abroad, if returned to the country within one year from the date of export and addressed to the exporter or his representative;

8. Parcels containing objects imported on the basis of claims for the replacement of defective goods, shipped free of charge within the period covered by the guarantee;

9. Pacels containing works of art or of science, privately owned by the addrssee--a local physical person;

10. Parcels containing moveable property for individual or family use by individuals settling in the country, should they arrive within three months from the date of settlement.

(2) Should the value of the content of the parcel, as per items 1 and 2 of the preceding paragraph, exceed stipulated limits, duty shall be paid on the entire value of the parcel.

(3) No customs fees shall be charged on parcels whose content has become unuseable because of damages or spoilage.

Article 22. (1) No duty shall be charged on the following:

1. Parcels whose content shall be worth no more than 10 leva, Bulgarian retail prices;

2. Parcels sent on a quarterly basis by Bulgarian citizens to members of their families residing abroad for purposes of employment, specialization, assignment, or training exceeding six months in accordance with the restructions stipulated in Article 23, paragraph 2 of the present ordinance.

(2) Should the value of the content of the parcel, as per items 1 and 2 of the preceding paragraph, exceed stipulated limits, duty shall be paid on the entire value of the parcel.

Article 23. (1) Parcels as per Article 21, paragraph 1.4, shall be duty-free should their overall value not exceed 100 leva, Bulgarian retail prices, and should they contain food products, clothing, shoes, and toys for the personal needs of members of the shipper's family located in Bulgaria. Clothing and shoes within a single parcel may not exceed one piece (pair, set) of each type.

(2) Parcels as per Article 22, paragraph (1) 2. shall be allowed to pass duty-free should their overall value not exceed 100 leva and should they contain items

for personal or family requirements. Clothing and shoes within a single parcel may not exceed more than one item (pair, set) of each kind while food products may not exceed a total weight of two kilograms.

(3) Should the content of the parcels as stipulated in the preceding paragraph exceed the stipulated limits, the surplus value shall be taxed in accordance with the Customs Tariff on the Taxation of Goods Imported or Exported by Physical Persons (DV, No 80, 1979).

Article 24. (1) The rayon or other customs offices, as stipulated by the Customs and Customs Control Directorate, shall open files for control over parcels as per Article 23.

(2) Files shall be opened at the request of the interested individuals submitted to the chief of the customs office in the area where the addressee (sender) maintains his permanent residence.

(3) The following documents must accompany the petition for the opening of a file: service note issued by the institution which has assigned the individual to a foreign country; declaration of family status of the employed (the specialist, the assigned individual).

(4) Should the addressee (sender) change his place of residence, the file may be transferred only by permission of the rayon customs office on the basis of a petition submitted in accordance with the preceding paragraphs.

Article 25. (1) In the sense of the presence ordinance the term family shall mean the following: spouse; minor children; children of legal age in the armed forces, full-time secondary or university students, the incapacitated, or individuals declared legally incompetent regardless of age.

(2) Parcels as per Article 22, paragraph (1) 2. may be shipped also by close relatives (children of legal age, parents, brothers, sisters, grandmothers, or grandfathers of either spouse) not considered members of the family in the sense of the preceding paragaph.

Chapter 4

Special Regulations for Sending or Receiving Certain Items

Article 26. (1) Gramophone records and taped recordings may be sent or received after hearing; printed matter must be checked.

(2) The export of manuscripts, negatives, slides, drawings, or photographs for publication in newspapers, periodicals or books, or for participation in exhibits or similar activities shall be allowed by permission of the Committee for Culture--Copyright Agency--and the Committee for the Press--Book Propaganda, Exhibitions and Fairs Directorate.

Article 27. (1) The shipping and receiving of pharmaceuticals shall be allowed on the basis of types and quantities permitted by the Ministry of Public Health.

The types and amounts of pharmaceuticals whose export is allowed are indicated in Appendix No 5. The import of pharmaceuticals shall be allowed on the basis of a prescription or a protocol issued by a medical institution.

(2) Permits for imports of pharmaceuticals may be issued and their prices may be determined by the pharmaceutical enterprises of the individual okrugs and the pharmacist at the Sofia Customs Office. The control-permit shall be noted on the prescription or protocol.

Concluding Stipulations

Only paragraph. The present ordinance is issued on the basis of Articles 29 and 75 of the Law on Customs and Article 78 of the Regulation on the Application of the Law on Customs, replacing the Ordinance on Customs Control and Customs Duties on International Postal Parcels of 1974 issued by the Ministry of Finance and the Ministry of Information and Communications.

Minister: B. Belchev

Appendix No 1 to Article 3, paragraph (1)

List of Customs Offices and Areas in Which Matters Related to the Export and Import of Items Through International Postal Parcels May Be Resolved

Customs Office	Area
Vidin	Vidin Okrug
Lom	Mikhaylovgrad and Vratsa okrugs
	Pleven Okrug
	Turnovo, Gabrovo and Lovech okrugs

Sofia Customs	Sofia, Kyustendil, Pernik and Blagoevgrad okrugs

The customs offices in Malko Turnovo, Kulata, Zlatareo, Stanke Lisichkovo and Gyueshevo will deal with problems related to the export of items by physical persons through international postal parcels exclusively for the settlement in which the corresponding customs office is located.

In addition to its activities in its stipulated area the Sofia Customs Office will control all small parcels arriving from the GDR, Poland, USSR, Hungary and Czechoslovakia whose wrapping bears the rombic seal. Such parcels shall be then sent directly to the post offices of their destination for delivery to the addressees (Article 7, paragraph 2).

Appendix No 2 to Article 4, paragraphs (2) and (3)

List of Objects Whose Import From and Export Into the Bulgarian People's Republic is Prohibited and of Items Whose Duty-Free Export From the Bulgarian People's Republic Through Postal Parcels is Prohibited

Section I

A. Items Whose Export From the Bulgarian People's Republic is Prohibited

1. Weapons, ammunition, military equipment, explosives, and inflammatory and other dangerous substances.

2. Narcotics and attachments for their use.

3. Objects of immoral content.

4. Goods for commercial purposes or production purposes; commodity samples.

5. Bank notes, coins, valuables and other foreign exchange valuable items as per Article 3 of the Law on Deals in Foreign Exchange Valuables and Foreign Exchange Control (ZSVTsVK).

6. Items, produce, or beverages in hermetically sealed containers (cans, etc.) concealing their content.

7. Cancelled or uncancelled mailing stamps and other philatelic materials with the exception of the cases and in accordance with the procedure stipulated in the Regulation on the Exchange of Postal Stamps with Foreign Countries.

8. Live animals with the exception of bees, leeches, silkworms, parasites and destroyers of harmful insects used for research purposes exchanged exclusively among officially recognized scientific institutes and establishments.

9. Printed matter, photographs, films, drawings, designs and other items whose shipping abroad could cause economic or other damage to the state; official publications and materials with restricted circulation and use.

10. Seeding and planting materials.

11. Antique objects and works of art such as paintings, drawings, portraits, sculptures, miniatures, carpets, tapestries, icons, church and household items, weapons, furniture, fabrics, decorations, clothing, manuscripts, books, musical instruments, craft instruments, coins made of precious and nonprecious metals, and other items of archaeological, antique or numismatic significance or considered ornaments of culture.

12. Objects whose shipping in postal parcels is forbidden in accordance with the stipulations of Ordinance No 4 on postal communications and the Universal Postal Convention.

13. Items whose importation is prohibited in the country of destination.

14. Persian-type rugs and carpets.

B. Items and parcels may not be imported into the Bulgarian People's Republic

1. Weapons, ammunition, military equipment, explosives, and inflammatory and other dangerous substances.

2. Narcotics and attachments for their use.

3. Objects of immoral content.

4. Goods for commercial purposes or production purposes; commodity samples.

5. Bank notes, coins, valuables and other foreign exchange valuable items as per Article 3 of the Law on Deals in Foreign Exchange Valuables and Foreign Exchange Control (ZSVTsVK).

6. Items, produce, or beverages in hermetically sealed containers (cans, etc.) concealing their content.

7. Cancelled or uncancelled mailing stamps and other philatelic materials with the exception of the cases and in accordance with the procedure stipulated in the Regulation on the Exchange of Postal Stamps with Foreign Countries.

8. Live animals with the exception of bees, leeches, silkworms, parasites and destroyers of harmful insects used for research purposes exchanged exclusively among officially recognized scientific institutes and establishments.

9. Printed matter, cliches, negatives, still and motion pictures, films, photographs, paintings, drawings, designs, manuscripts, records or recorded tapes, and others which may be politically, economically and ideologically harmful to the socialist state.

10. Gift parcels containing used clothing, shoes, bedding, covers, or bed covers.

11. Used motor vehicle tires.

12. Shipments by foreign companies with the exception of the cases stipulated in Article 66 of the PPZM and Note 3 of the list.

Note 1. Items confiscated for moral, health or political reasons shall not be returned.

2. Parcels as per item 10 shall be returned to sender at his expense.

3. The prohibition as per item 12 shall not apply in the following cases:

a. Postal parcels containing objects worth no more than 50 leva, Bulgarian retail prices, providing that receipt of the parcel does not originate any obligation on the part of the local resident to the foreign company;

b. Should the object be ordered from a foreign country as per Article 7, letter "b" of the Ordinance on Foreign Currency Deposits by Local Residents.

4. Foreign currency and other valuables received by local residents in postal parcels must be submitted to the Bulgarian National Bank (Bulgarian Foreign Trade Bank) within 14 days of the date of receival (Article 20 of the Ordinance on Border Control of Valuables (NGKVTs), DV, No 59, 1966). Bulgarian leva included in international postal parcels shall be submitted to the Bulgarian National Bank for deposit as state revenue (Article 20 of the NGKVTs).

Section II

Items whose duty-free exportation from the Bulgarian People's Republic is prohibited.

1. Clothing for babies and children, including knitted goods and babies' and children's shoes.

2. Unbleached calico and sheeting and their products--bed sheets and pillow cases.

3. Meat products.

4. Dairy products.

5. Vegetal and animal fats.

Remark. The prohibition does not apply to cases stipulated in Article 22, paragraph 1, point 2, of the ordinance.

DEVELOPMENT OF AGRARIAN ECONOMY SINCE 1944 REVIEWED

Sofia SPISANIE NA BULGARSKATA AKADEMIYA NA NAUKITE in Bulgarian No 4, 1980 pp 52-61

[Article by Prof Nikola Palagachev: "Development and Achievements of Agriculture in the Course of 35 Years of People's Regime"]

[Text] The 9 September 1944 victorious uprising is the most profound revolutionary event of the entire almost 1,300-years-old Bulgarian history. It marked the defeat of the fascist dictatorship, the overthrow of the bourgeoisie and the victory of the democratic forces rallied within the Fatherland Front, headed by the communist party, who assumed responsibility for the further fate of the country.

In the course of 13 centuries Bulgaria has had a number of general or partial revolutions. The acceptance of Christianity in 865 and the beginning of the dissemination of the Slavic-Bulgarian alphabet were of revolutionary significance. The liberation of the country from the Turkish yoke, which put an end to the feudal system and gave scope to the development of the bourgeois society, was another social revolution.

However, against the background of all historical events the 9 September revolution is of outstanding grandeur as the most decisive and broadest possible revolution which not only defeated fascism and capitalism but became an event leading to the implementation of the loftiest aspirations, strives, and hopes of the brightest minds of the country and of the fighters for freedom and progress during the centuries. The 9 September victory laid the beginning of deep changes which marked a turn in the overall course of all previous Bulgarian history.

These have been 35 years of free creative life. Revolutionary changes on the way to socialism are continuing in all the areas of the material and spiritual building of a new life in Bulgaria.

The changes which occurred in the development of Bulgarian agriculture play a particular role in the overall constructive progress. This special role is defined not only by the great successes in agricultural output. The socialist reorganization of agriculture occurred with the creative application of the Leninist cooperative plan. It became a leading experience, a contagious experience for many countries.

Great difference in agrarian relations and in the levels of development of agricultural production exist in the various parts of the world.

The changes which took place in the development of Bulgarian agriculture on the way to its industrialization indicate one of the means for the reorganization of small private farming aimed at the effective solution of the complex agrarian problem under Bulgarian conditions. At all times the agrarian problem has been one of the theoretically most complex and most acute political problems most closely affecting the destinies of millions of rural people. In practical terms, the progressive and democratic structure of agrarian relations remains one of the most important and most sensitive problems of our time. The new way and example indicated by the socialist countries in this respect are among the most significant phenomena in the historical development of the world after 1917.

The Bulgarian People's Republic as well took this new path of development. In the course of the past 35 years it changed from a backward agrarian country into an advanced industrial-agrarian state.

At the end of World War II, following the victory of the people's system on 9 September 1944, the state's policy was directed toward the following objectives: insuring the feeding of the population by achieving at a faster pace the satisfaction of consumption requirements based on scientific nutrition norms; meet the needs of industry for agricultural raw materials; intensify Bulgaria's participation in the international division of labor by steadily increasing exports of agricultural commodities, both fresh and processed; and resolve within a short time the social problems facing the Bulgarian countryside through the elimination of major disparities between town and country and between agricultural and industrial labor.

Small private farming was unable to meet such requirements. It had to be converted into large-scale, mechanized and highly profitable farming.

The socialist reorganization of agriculture in our country was completed relatively quickly. The difficulties paralleling this reorganization were successfully surmounted as well. A decisive role in this respect was played by the clear theoretical line provided by the BCP and its leader G. Dimitrov, which emphasized the following basic stipulations:

The main prerequisite is available: A people's democratic system, headed by the powerful alliance between the working class and the toiling peasants with the leading role of the workers;

The nationalization of the land is not a mandatory prerequisite for the socialist reorganization of agriculture. The preservation of the private ownership of the land and rental payments do not hinder but assist the cooperativization process;

The agrarian reform eliminated the biggest land owners. However, it was unable to eliminate small-scale farming or to heal its organic ills: poverty, hired labor, leasing of the land and other forms of exploitation;

Under socialism the nature of the cooperative changes. Cooperative organizations and enterprises assume a socialist nature. They become similar to state enterprises despite certain differences;

Given the existence of the Soviet Union and its powerful industry, the socialist reorganization of Bulgarian agriculture became possible without awaiting the process of industrialization as was the case with the collectivization of Soviet agriculture.

The scientific analysis provided by G. Dimitrov of the general and the specific aspects of the socialist reorganization of agriculture eliminated unnecessary confusions and hesitations. The specific conditions of Bulgarian agriculture merely concretized the ways and means without reducing the effectiveness of the general principles governing the application of Lenin's cooperative plan. Thus, Lenin's general concepts obtained a new development and increased their power and influence over the reorganization of the old Bulgarian agriculture.

By providing an accurate theoretical substantiation of these basic landmarks, G. Dimitrov directed the party along the true practical way for the solution of one of the most difficult problems facing the economy of any country—the agrarian problem.

When we speak of the structuring and development of our cooperative system, we must not forget the particularly valuable experience of the peasants in the area of the cooperative movement. Long before the people's victory the peasants extensively participated in the development of various types of cooperatives, including production cooperatives. Under the influence of developing socialism in the USSR, before 9 September 1944 our country had set up over 40 production agricultural cooperatives of which 29 had remained by 9 September 1944. Thus, under the leadership of the BCP, the development of the cooperative movement in our country in the areas of credits and consumption was extended to agricultural production as well. Under the bourgeois system and capitalist conditions, the agricultural production cooperative appeared in our country following the example of the kolkhozes. Along with the remaining cooperative organizations it assumed its position as an economic organization aimed at unifying the progressive forces in the Fatherland Front. It became an effective school for the reeducation of the peasants in a collective spirit. Such party activities yielded abundant results: A tremendous capital was accumulated which, under the people's system, provided a powerful impetus and accelerated the cooperativization of the farms.

The great popularity and influence of and faith in the BCP in the villages was a powerful factor for the accelerated process of the socialist reorganization of agriculture in our country. At this point let us strongly emphasize the role of the people's intelligentsia, raised by the party and tempered in battle, rallied within the union of Bulgarian agronomists, systematically fighting in defense of the rights of the peasants, educating and directing the specialists, starting with the university, loyally to serve the people. The members of the society led the progressive mass organizations of tobacco growers, vine growers, livestock breeders, the cooperative organizations in the villages, and so on. Trained in this fighting school, and having participated in the struggle waged

by the entire people against facism, agronomists, veterinarians, teachers, and cooperative workers enthusiastically began to work, with the dawn of freedom, for the reorganization and development of Bulgarian farming. This played an important role not only in the pace of cooperation but in the collective management of the TKZS [Labor Cooperative Farms] and the DZS [State Farms].

The development of Bulgarian agriculture may be divided into five stages in terms of concentration, specialization and integration:

The first stage (1944-1948) may be described as that of restoration: surmounting the damages caused by the war period.

The second stage (1949-1952) is a revolutionary period in agricultural reorganization. It was a time of the first mass collectivization and over 60 percent of the land to be brought into the cooperatives became socialized. Machine-tractor stations (MTS) were set up. Socialist ownership of productive capital became the standard base for industry and agriculture.

The third stage (1953-1958) was that of strengthening and further cooperativization of agriculture. It was a period of the total victory of socialism in the Bulgarian countryside. This concluded the overall cooperativization and socialization of production in agriculture on a socialist basis. The material and technical base expanded and the disparity between the development of production forces and existing production relations was largely surmounted. This could be accomplished thanks to the substantial material aid provided by the USSR during that period through deliveries of agricultural equipment.

The fourth stage (1959-1969) was the stage of the further strengthening and concentration of production into larger production units and enterprises, conversion to high-pace production intensification, increased specialization and enhancement of the effectiveness level. The average size of agricultural enterprises (TKZS and DZS) rose from 3,000-12,000 decares by 1958-1960 to 38,000-42,000 decares of arable land. During that period a sharp increase in the role of chemization, irrigation and mechanization was the main line of intensification. In 1965-1967 7.5-12.6 kilograms of chemical fertilizers (in terms of active agent) were applied per decare of cultivated land. Bulgarian and foreign high-yielding and high-grade strains were applied. Qualitative changes in the material-technical and production base and the combination of biological factors with chemization, irrigation and mechanization, achieved in that period, led to high and relatively stable yields from basic farm crops.

The fifth and current stage began in 1970. Its characteristic features are even higher rates of production intensification with the accelerated application of industrial technologies and production and management methods. The April 1970 BCP Central Committee Plenum adopted an expanded program for a new concentration of agriculture and for its development on an industrial basis. The Agroindustrial Complex (APK) was established as the basic form of concentration of agricultural production at this stage.

The Agroindustrial Complex is developing as the basic organization through whose continuing development the following basic problems are resolved:

The improved location and acceleration of the process of specialization and concentration as the base for large-scale machine production in farming;

Improved agricultural integration and integration between agriculture and the other sectors of the national agroindustrial complex;

The resolution of the economic, social and living problems which equalize the conditions between town and country on a high scientific and technical level in accordance with the requirements of the developed socialist society;

The training of cadres--managers, specialists and operational--for industrial agricultural production.

According to NAPS [National Agroindustrial Union] data in 1979 agriculture was organized in big agricultural enterprises as follows: agroindustrial complexes (APK) numbering 275, with an average size of arable land of 131,300 decares; scientific-production viticultural-wine-making complexes (NPLVK): eight with 145,100 decares; a fruit and vegetable complex with 309,200 decares; NPK [Scientific-Production Complex] and DSS [State Seed-Growing Farms] of the Grade Seeds DSO [State Economic Trust]: 34 with 38,400 decares; NPK of the NPO [Scientific-Production Trust] for cattle and sheep breeding: 14 with an average size of 36,000 decares of arable land.

The APK are the basic territorial economic units which are systematically and purposefully acquiring a system of intensive industrial agricultural production. Consequently, the establishment and development of the APK will contribute to the solution of the basic problems related to building a developed socialist society.

The solution of the agrarian problem, the industrialization of the country, the development of agricultural science and the training of specialists offered opportunities for the utilization of resources and provided scope for the steady improvement of technology and the application of technical progress in agricultural production.

Agricultural science plays a decisive role in determining the possibilities of available resources and technologies. Its development is most closely linked with the development of socialist agriculture and the achievements of world science. The agricultural scientists are extensively using the experience and discoveries of other countries and are developing themselves specific scientific problems related to our agricultural production. The country has a widespread network of 56 scientific institutes and experimental stations in the field of agriculture. They have specialized in accordance with typical natural and economic conditions. They employ over 1,800 scientific workers. Under the people's system agricultural science in Bulgaria was able to achieve considerable successes. So far, 484 Bulgarian strains and hybrids have been developed, 284 of which have been applied. After investigation under our conditions, a number of foreign strains and hybrids of corn, wheat, sunflowers, barley, and others have been used as well. Soviet Bezostaya 1, Avrora, and Kavkaz wheat strains and Peredovik, Smyana and Mayak sunflower strains have become quite popular.

New industrial technologies have been developed and are being applied for growing wheat, corn, sunflowers, tobacco, cotton, grapes, vegetables, and others. Our selected strains come close to the best world standards. Particularly valuable are the winter wheat strains Sadovo 1, Ludogorka, Levent, Rusalka and others, the Knezha corn hybrids, and cotton, tobacco, and other crop strains.

Large-scale soil maps have been charted (1:25,000 and 1:400,000) and the availability of variable forms of nutritional elements in the soils has been established. The building and equipment of the Soil Fertility Institute were expanded in cooperation with the FAO. The institute is engaged in soil studies domestically and abroad.

Considerable successes have been achieved in the area of plant protection. The most successful methods for fighting crop diseases and pests are being used. A beginning has been laid to the development of suitable and means for waging the struggle with biological agents.

Our animal husbandry science has made a practical contribution to the development of new and highly productive farm animal breeds, animal nutrition, and so on. Bulgarian veterinary science has achieved great accomplishments as well. Particularly noteworthy is our experience in the development of new breeds of farm animals. The specific complex scientific collectives which were organized developed within a short time valuable highly productive breeds of cattle, sheep, hogs, and other farm animals.

The agroeconomic science developed a number of basic problems of large-scale output. Zoning, forecasting, price-setting, payments, norms, and others are of decisive importance to the victory of the cooperative system and the intensive development of agriculture.

The successes and scientific achievements of ouragriculture are directly related to the development of a system of specialized scientific research institutes and experimental stations.

Bulgarian agricultural science is most closely linked with the intensification and industrialization of agricultural output. The participation of Bulgarian scientists and specialists in the training of agricultural cadres in higher educational institutions and in secondary and practical schools plays a particular role in this direction.

Bulgarian agricultural science and cadre training developed and are continuing to develop dynamically in very close cooperation with world science and practice.

The major and basic structural changes which occurred in Bulgarian agriculture were accompanied by a radical change in technical facilities. Forces and means were focused on irrigation, chemization, mechanization, use of new crop strains, and accelerated upgrading of livestock breeds. Let us strongly emphasize the efforts made to insure the comprehensive use of these four directions of technical progress in farming with a view to obtaining maximum results.

Table 1. Development of Agricultural Intensification

	1952	1960	1975	1978
Capital investments in agriculture per 100 hectares arable land, leva	1561	7801	16472	16627
Tractors (in terms of 15 hp) per 100 hectares arable land, number	2.6	8.3	28.8	32.1
Chemical fertilizers in pure substance per 100 hectares arable land, kilograms	415	3206	14327	15586
Total output per 1,000 decares arable land, leva (comparable prices)	34000	52000	102559	106260

[1]"Statisticheski Godishnik na NRB" [Statistical Yearbook of the Bulgarian People's Republic], 1979.

The productive capital per hectare of arable land rose from 362 leva in 1939 to 1,270 leva in 1975. From the qualitative viewpoint the changes are even more startling. The bulk of the old and primitive capital assets was replaced by new and more advanced tools: draft cattle, and iron and wooden plows were replaced by tractors; animal-pulled carts were replaced by motor vehicles; pack animals were replaced by machines, and so on.

In about 25 years the number of tractors (on the basis of 15 hp) rose by a factor of 15: from 8,657 in 1950 to 136,551 in 1975. Until 1950 there were no combines in agriculture. Today there are 22,562. In 1970 there were 63 hectares of arable land per tractor (15 hp); the ratio rose to 35 hectares in 1975, thus reaching the level of other countries whose ratios are as follows: GDR, 34.5; Czechoslovakia, 27.4; France, 17.9; Britain, 20.9; Italy, 28.0; and United States, 36.7 hectares.

The development of the material and technical base and of production forces in agriculture took place rapidly. All agricultural intensification factors have been developing at a fast pace (see Table 1).

Between 1960 and 1975 power availability in agriculture quadrupled. It doubled within a 10-year period (1965-1975) (see Table 2).

Table 2. Power Availability in Agriculture (per 1,000 decares arable land, hp)[1]

Year	All category farms: Mechanical engines and draft cattle	All category farms: Including mechanical engines
1956	42	27
1960	65	56
1965	104	97
1970	148	142
1975	199	194
1978	229	224

1. Statisticheski Godishnik na NRB, 1974, 1976, 1979.

Table 3. Overall Agricultural Output[1] with 1960 = 100

Year	Total	Per Capita	Crop Growing	Per Capita	Animal Husbandry	Per Capita
1960	100,0	100,0	100,0	100,0	100,0	100,0
1965	117,1	112,2	112,1	107,5	127,3	121,9
1970	138,6	128,4	133,3	123,5	149,5	138,5
1975	160,1	144,3	144,1	130,0	191,2	172,5
1978	165,6	147,9	143,9	128,5	206,8	184,5

Milk per cow	450	1453	2211	2264	2245
Wool per sheep (grams)	1511	2429	3300	3800	3819

1. Statisticheski Godishnik na NRB, 1979.

The growth and qualitative changes of production forces in agriculture triggered substantial changes in the volume, structure, and pace of agricultural production (see Table 3).

The increase in agricultural output was achieved through intensive means only--by raising yields and animal productivity and increasing labor productivity (see Tables 3 and 4).

Thanks to the comprehensive use of science and technology, agriculture is successfully developing and has achieved remarkable successes in terms of the growth of overall output and increased production effectiveness. On the basis of comparable prices, between 1939 and 1976 overall agricultural output rose by a 2.5 factor. Between 1960 and 1975 overall agricultural output rose 161 percent while overall food output rose 289 percent. In terms of current prices agricultural output per capita rose from 309 leva in 1960 to 495 leva in 1970 and 557 leva in 1975.

Compared with 1948 the 1975 national income from agriculture had nearly quadrupled (3.8). It was double the 1960 output. Between 1960 and 1977 exports of agricultural commodities rose by a 2.5 factor or, together with food industry exports, by a factor of 4.8.

Bulgaria has increased its food production considerably. Thus, for example, on a 5 year average (1966-1970), compared with 1961-1965, its food production rose 131 percent whereas other averages were as follows: global, 115 percent; GDR, 120 percent; Hungary, 116 percent; Czechoslovakia, 114 percent; United States, 113 percent; France, 112 percent; Greece, 126 percent. Compared with 1961-1965, the same output for the 1971-1975 rose 139 percent in Bulgaria, 129 percent globally, 134 in Czechoslovakia, 132 percent in the GDR, 145 percent in Hungary, 127 percent in the United States, 125 percent in France, and 148 percent in Greece. Average productivity of basic crops and livestock increased several hundred percent compared with the prewar level. In terms of average wheat, corn, and sunflower yields Bulgaria ranks with countries with the highest average yields such as Denmark, The Netherlands, France, Canada, the United States, the GDR, Hungary, and others.

Labor productivity in agriculture has been rising steadily. It rose by a 3.7 factor between 1961 and 1975.

In 1978 there were about one million people employed in agriculture or 24.5 percent of the total working force in the country. However, it accounted for over 36 percent of all commodity stocks in domestic trade and about 30 percent of exports. Between 1976 and 1978 the average output from a total of 47 million decares of arable land was as follows: grain, 8 million tons; fruits, 2 million tons; vegetables, 1.6 million tons; meat, 700,000 tons; and oriental tobacco, 118,000 tons. Achievements in the development of agriculture and the food industry enabled us to successfully resolve two basic problems of our national economy: first, to insure the supply of the population with farm products, fresh and processed, in accordance with enhanced living standards; second, to allocate considerable quantities of agricultural products for export. In terms of the production of basic food products per capita the Bulgarian population is far above average global data and is equal or close to the levels of the most developed countries. The production of some goods per capita in the world and in the country in 1976 was as follows:

	Global	Bulgaria
Grain	378	978 kilograms
Meat	29	84
Milk	107	207
Eggs	5.9	10.6

The highest indicators for grain are those of the United States with 1,200 kilograms, Denmark with 1,165 kilograms, and Sweden with 670 kilograms. For meat the highest indicators are those of Denmark with 212 kilograms, The Netherlands with 130 kilograms and the United States with 116 kilograms. For milk: Denmark with 1,025 liters, The Netherlands with 768 liters and France with 564 liters.

The rates of increase in the production of food clearly indicate that by 1980 the scientific nutritional norms will be reached for basic staples; in the case of individual products this will be achieved in the 1981-1985 Five-Year Plan (see Table 5).

Table 5. Nutritional Norms and Consumption of Basic Food Products (kilograms, pieces, liters)

Product	Scientific norms based on December program	1978	
		Per capita Production	Per capita Consumption
Meat and meat products	80.0	82	61.1
Fish and canned fish	10.0	..	7.0
Milk and dairy goods	360.0	220	156.9
Eggs	265.0	252	197.0
Vegetal oils	13.0	..	14.1
Flour	100.0	300	155.6
Rice	4.0		4.2
Beans and other leguminous	6.0		4.0
Sugar and confectionary goods	32.0		35.0
Vegetables, total	180.0	200	93.8
Potatoes	40.0	44	23.1
Fruits, total	200.0	230	112.5

An entire set of indicators characterized strength and dynamics of our socialist agriculture. A great deal has been achieved compared with capitalist Bulgaria and with a number of nonsocialist countries throughout the world. However, looking ahead and assessing our achievements on the basis of the criteria of mature socialism, our conclusion would unhesitatingly be that such achievements are merely one of the numerous important steps of progress. Displaying new tireless revolutionary enthusiasm, the party is opening new horizons and pointing at new peaks. Age-making new scientific accomplishments of the human genius are being implemented in the socialist society and consciously used for the good of man. The new horizons in agriculture are particularly important today, when the peoples of the world are struggling for the preservation of the peace and against unemployment, poverty, food shortages, harmful living conditions, environmental pollution, housing shortages, and so on.

Today the world's population exceeds four billion of which about 40 million die of hunger every year. Predictions indicate that by the year 2000 the population on earth will total 7.5 billion. In order to maintain the present nutritional level agricultural production must be doubled. As a result, one billion people will be hungry and the number of those who die of hunger will rise from 40 to 80 million people. In order to improve human nutrition throughout the world the production of food must at least quadruple. These most general figures alone indicate the great importance of agriculture.

This makes the successes of our socialist agriculture even more important as the basis for the future development of our output.

The forecasts on the development of agriculture and the food industry by the year 2000 are based on the scientific and technical achievements of Bulgarian and global agricultural science. In most general terms, scientific predictions are characterized by the following indicators: By the year 2000 overall agricultural output will rise by a 2.2-2.5 factor compared with the 1971-1975 average annual data while net output will rise, respectively, by a factor of 2-2.3. Such predictions are based on the rational utilization of land, water, and fuel resources in the country and the steady improvement of current and future farming technologies. They call for the conservation of labor and materials per unit of output through improved biological, technical, organizational, economic and social production factors.

Current experience in this direction confirms the reliability of the indicators included in the forecast and the plans. In 1977 alone agriculture and the food industry applied 244 scientific and technical accomplishments with annual economic savings totaling 150 million leva. The more important among them are the following: 188 new or improved technologies with annual savings of 60.8 million leva; and 14 new or improved various crop strains with annual savings of 40.2 million leva.

The scientific and technical forecasts formulated for 1990-2000 call for the application of scientific achievements in production yielding considerable savings. This includes new soil cultivation systems, 114,000 leva; new wheat strains, 80,000 leva; cold-resistant grapevines, 5.6 million leva; new irrigation technology, 10.6 million leva; technologies for industrial tomato production, 11.4 million leva; technologies for industrial fruit production, 8.2 million leva; and technology for industrial fodder production, 10.2 million leva.

The basic directions followed in the development of science and technical progress in agriculture in the Eighth Five-Year Plan (1981-1985) and through 1990-2000 are the following: To insure the most rational utilization of the land and the biological possibilities of farm crops and livestock. Priority will be given to research for determining the genetic-production classification of soils, regulating circulation of nutritional substances in the soil for the development of optimum fertilizer norms; the improvement and development of new industrial technology in crop growing; the application, development, and utilization of new strains; the intensification of research on biological means for fighting diseases and pests; the establishment of a biologically and economically optimum irrigation regimen and the extensive application of highly productive machine systems; the improvement and development of new industrial technologies in animal husbandry and fodder production, and the expansion and improvement of hybrid animal husbandry.

Cadre training--scientific workers, specialists with higher and secondary training and highly skilled production experts--will face new requirements.

The implementation of the 1990 program, on a longer-range basis, will greatly depend on the resolution of the problems facing Bulgarian science and its successful cooperation with world science.

5003 CSO: 2200

RESULTS OF COAL RESERVES STUDIES DISCUSSED

Sofia SPISANIE NA BULGARSKATA AKADEMIYA NA NAUKITE in Bulgarian No 4, 1980 pp 31-45

[Article by Academician Yovcho S. Yovchev: "On the problem of Bulgarian Raw Material Fuel-Energy Potential Related to Extractable Coal Discovered in the Country"]

[Text] Following the liberation of Bulgaria from the age-old yoke of the Ottoman Empire, one of the many problems to be resolved by the young capitalist state was the study of the geological structure of the country with a view to the search for minerals. Naturally, even under the Turkish rule, particularly following the powerful development of capitalism which began following the French revolution, the problems of the raw material base in the highly developed capitalist countries were among the first requiring a solution for such development. Naturally, even before that time countries such as England (one of the most developed countries at that time) were interested in this problem which was the basis for the development of great interest in colonies displayed both by England and the remaining capitalist countries. It is particularly now, in the age of development of imperialism, that the factor of extractable raw materials is of decisive global significance which could be noted today by any politician, economist, or even common man, for the latest crises developing today under capitalism are also related to raw material problems.

Published data show that before the liberation of our country scientists from the Western countries came to study the geological structure of the Balkan Peninsula ruled by the Ottoman Empire. They included scientists from France, Germany, and Austria-Hungary, countries which, to one or another extent, were interested in the raw material problem as a main factor. However, studying the geological structure as a first stage, they greatly contributed to the study of Balkan geology.

These studies made it possible to undertake, as early as the 1860s, an attempt to summarize Balkan geology. This was most successfully accomplished by the French geologist Ami Boue who synthesized the material in such a way as to chart the first geological map of the Balkans.

It is accepted that the beginning of studies of the geological structure and of minerals in the country started in the 1880s, following the appointment of

the first geologist in the country, G. Zlatarski. However, due to the lack of funds unavailable to the Bulgarian youth, he was unable to organize and develop geological studies in Bulgaria. He studied individual problems of the geological structure of the country and publications on geological research in the Balkans. His main task, however, as head of the geological service, was to supply information to those who were interested at that time in the opening of quarries and chart and protect perimeters.

At the beginning of the 20th century a small number of geologists began to work more intensively on the geological structure of the country, particularly when the work was joined by Professors G. Bonchev, L. Vankov, St. Bonchev, and others.

At that time G. Zlatarski was intensively working on summarizing the published geological material, as a result of which he charted the first geological map of the country on a scale of 1:300,000. Naturally, however, the studies were conducted within the limits of the possibilities of the state and of the necessary financial means used for the procurement of equipment and cadre training. However, the state was unable to allocate the necessary funds for major geological studies of minerals and the discovery of coal, ore, and nonmineral deposits.

Let us note that almost simultaneously with the charting of the geological map by G. Zlatarski, the Serbian geomorphologist and geographer Yovan Tsviych, working on Balkan geomorphology, visited Bulgaria, as a result of which he provided the first morpho-tectonic geological outline of the country which consisted of a morpho-tectonic zoning.

Still at that time individual coal and, partially, ore extraction were taking place on a significant scale. Somewhat later more significant coal extraction was developed, for the needs of the railroads increased and in order to avoid coal imports.

However, a considerable impetus in the exploitation of minerals was noted after the first imperialist war, between 1918 and the liberation of our country from capitalism and fascism on 9 September 1944. Within this relatively long period coal extraction for domestic needs, mainly for railroad transportation and, partially, for fuel for the urban population, increased. Many new private and a lesser number of state perimeters were developed, including coal basins and ore deposits most of which exploited by private and foreign capital. At that time the biggest coal extraction areas were the Pernik State Mine followed by Bobov Dol, Maritsa-Zapad, Pirin, the Burgas Mine and the Balkan Mines.

However, even at that time reserves of coal and ores, for whose study the necessary funds were not allocated, were insignificant. The Pernik State Mine alone had greater funds available as a result of which that basin showed certain industrial deposits. Somewhat later, toward the end of the period, certain yet minor studies were undertaken of coal deposits in other state mines and even in some privately owned deposits.

A similar situation prevailed in the case of ore deposits, even though the scale of prospecting within that period was considerably lower. The Granitoid Company alone allocated some funds for studies. This led to the discovery of possibilities at the Pirin Mine and the ore deposits in the Rodopi Mountains.

In the interest of truth we must note, when discussing cadre possibilities in the area of the extraction and study of minerals and the detailed study of the geological structure of our lands, that the country had relatively well-qualified engineers and technicians, particularly in the period following World War I. They included engineers Konyarov, S. Toshkov, B. Radoslavov and many others. Some of them, studying the problems of the geology of minerals and their forecasts, wrote a number of interesting summarizing works. For example, Engineer Konyarov wrote interesting works on coal and iron ore deposits; Engineer S. Toshkov was the first to write a book on mineral ores. Many other engineers published individual articles on the extraction of minerals and, in some cases, on their geology.

During that period a substantially greater number of works were published on the country's geological structure. Particularly noteworthy were the works of scientists and geological specialists such as G. Zlatarski, G. Bonchev, L. Vankov, St. Bonchev, P. Bakolov, Str. Dimitrov, El. Koen, Ts. Dimitrov, Ek. Bonchev, V. Tsankov, B. Kamenov, R. Beregov, A. Yanishevski, Sht. Zhelev, and many others. This galaxy of scientists and specialists was the aktiv of our country engaged in the study of its geological structure before our liberation from capitalism on 9 September 1944. Let us note that other than the works of Konyarov and some others no major or serious summarizing works on mineals have been published.

Toward the end of that period there was no scientifically deeper synthesis of the geological structure of the country. However, the need for such a synthesis of the geological structure and of minerals became particularly urgent after 9 September 1944. That is why, on the recommendation of Soviet scientists and specialists, it was suggested that the geological service which existed until 1948, headed by Ts. Dimitrov, to be assigned such a summation on the basis of all available data related to the country's geology and mineral deposits. This was assigned to a collective headed by Dr Koen and Ts. Dimitrov, with the participation of Str. Dimitrov, Prof G. Bonchev, Prof V. Tsankov, Prof B. Kamenov and some others. The result of their efforts was a major work on the foundations of Bulgarian geology with a geological map on the scale of 1:500,000, charted by B. Kamenov and edited by El. Koen. This work was the basis for the establishment of the geological service and related to the further detailed study of the geological structure and minerals in the country. It has still not lost its scientific significance.

Such was the situation of the geological knowledge about the country and the state of the study of minerals before 9 September 1944.

Let us cite a few figures to illustrate the condition of the insufficient study of a great variety of minerals over this long period of capitalism following the liberation, for no such figures have been provided. Thus, for example, ore deposits, mainly polymetallic in the Rodopi ore deposit area were assessed at one million tons; copper ores, several tens of thousands of tons; iron ores, several hundred thousand tons; lignites, 214 million tons; hard coal, 150,200 tons; anthracite, several tens of thousands of tons. The annual output of all types of coal did not exceed 3-3.1 million tons; lignite extraction did not exceed 80,000-100,000 tons; brown coal, 2.7-2.8 million tons; hard coal, about 160,000 tons; and anthracite, about 15,000-20,000 tons.

Naturally, such reserves could not constitute a foundation for a socialist industry and, particularly, of heavy industry such as the power industry, metallurgy, chemistry, construction, and machine building, without which the development of the country's economy under socialist conditions was impossible. This made it necessary for the people's regime, the BCP Central Committee, the Fatherland Front and the government to resolve, as the first and immediate task, problems related to the development of the necessary mineral raw material base. This was undertaken gradually, after the people seized the power.

However, the decision of the Fifth BCP Congress provided at that time a particular impetus for the solution of the problem. It substantiated the need for the development of a socialist industry and the measures which had to be taken in mining and geological surveys. However, the development of this project in accordance with the implementation of these decisions in such a major area required large funds which were unavailable to our country at that time. Thus, for example, the need for funds, cadres, equipment, preparatory and laboratory facilities, and so on, required that the necessary steps be taken for normal geological surveys despite such difficulty conditions. Let us note here, yet once again, that the geological surveys conducted under capitalist conditions, particularly regarding the study of minerals, were on a very low scientific-methodical level. This particularly applied to the absence of any scientific-methodical base: the lack of highly skilled cadres and the virtual absence of equipment and instruments. Under such conditions we were unable to implement the decisions of the Fifth BCP Congress. These problems could be resolved only with Soviet help.

That is why we asked for USSR help which was granted. In order to carry out our assignments the country's geological service had to be reorganized on the basis of the new Soviet scientific principles governing geological work in the country, after which the general lines of work had to be earmarked along all basic directions. This included the detailed study of the country's geological structure, and geological surveys to determine the deposits of coal, ores, and nonmineral deposits the respective geological prerequisites and criteria for which existed in the country. In order to implement all this, at the beginning of 1948, following the reorganization of the geological survey service, we were given Soviet aid which, considering the particular urgency of the need to rapidly find and prove the existence of industrial deposits of nonferrous and ferrous metals, had to be used most efficiently. For this reason it was concentrated on the study of polymetallic deposits in the Rodopi Mountains and of copper in the Burgas area. To this purpose a Soviet geological expedition was set up consisting of Soviet and Bulgarian specialists. Later, toward the end of 1949, the expedition was assigned the study of petroleum and gas deposits in northeastern Bulgaria. Our geological survey service dealt with all remaining types of ores and with nonferrous metals outside the Rodopi ore deposits area and the Burgas ore deposits region. Tremendous geological survey operations were launched for virtually all types of minerals and for the geological mapping of the country on a scale of 1:25,000 and 1:100,000.

As a result of all this, at the beginning of the 1950s surveys for coal and ore and nonmineral deposits began to yield specific positive results: Coal reserves grew extensively and reserves of polymetallic ores, copper, ferrous metals and nonmineral deposits and construction materials increased sharply. Substantial

coal deposits were found in the already known East Maritsa Basin and in the other already known coal basins. The first petroleum deposit was discovered. Great reserves were discovered of gypsum, kaolin, fire-proof clays, and a number of other nonmineral deposits and sources of construction materials. In that period the basic deposits for the development of a ferrous metallurgy were discovered as well--the Martinovo and Krumovo iron ore deposits and, particularly, the Kremikovtsi deposits. This largely resolved the problem of the development of our ferrous metallurgy. At that time we also discovered industrial deposits of polymetal ores. This enabled us to develop our polymetal industry and the discovered copper ore deposits enabled us to develop our copper extraction industry, the chemical industry, and the construction industry, on a broad scale, particularly in terms of cement, fire-proof materials, the porcelain and glassware industries, and many others. The construction of a number of big coal mines and electric power plants was undertaken on the basis of the coal deposits.

The historical April 1956 plenum played a particular and a decisive role in this new major impetus given to the development of geological surveys and the development of heavy industry. We were helped by Comrade T. Zhivkov personally in the implementation of its decisions related to the geological survey of the country. This enhanced the enthusiasm of the geological surveyors, as a result of which the new petroleum and gas deposits were discovered in the central and western parts of northern Bulgaria. In connection with the developed geological surveys for petroleum and natural gas a number of survey drills were made leading to the discovery of the Dobrudzha coal basin with its very big coal deposits. Other such drills led to the discovery of substantial gypsum deposits in the vicinity of Vidin and Oryakhovo and of the big manganese ore basin near Obrochishte Village in Tolbukhin Okrug. All in all, the results of the search for petroleum and natural gas led to the discovery in northern Bulgaria of no less than 20 hot mineral water springs, mainly in the coastal areas of Varna and Tolbukhin okrugs.

The geological studies related to the mapping of the country resolved a number of important regional geological problems while the materials of the studies were summarized as a result of which a number of proper standard works were created together with a number of very important geological documents such as the various types of geological maps on scales of 1:25,000, 1:50,000 and 1:100,000. On this basis the following geological maps covering the entire country were charted and published: A 1:200,000 scale geological map of the country; a 1:200,000 scale tectonic map of the country; and a 1:200,000 scale gravimetric map. On the basis of these fundamental geological documents and materials obtained on the country's hydrogeology, a hydrogeological map of the country on a scale of 1:200,000 was issued together with two other specialized hydrogeological maps on a scale of 1:200,000.

Special metalogenic maps were charted as follows: Metalogenic zoning of Bulgaria on a scale of 1:500,000; metalogenic-forecast maps for ferrous and nonferrous metals on a scale of 1:500,000; forecast (area) maps on coal deposits and a petroleum-natural gas map on a scale of 1:500,000. All these metalogenic and other maps and the map of minerals on Bulgarian territory were based on the geological map on a scale of 1:500,000. All this shows that the foundations were laid for new directions in the search for basic types of minerals.

Since 9 September 1944 no less than 1,000 works have been published on the country's geological structure; the Central Geology Fund of the Committee for Geology received about 7,000 papers as a result of studies reflecting our work on geological surveys with a detailed study of the geological structure of the country and its minerals.

Today we may be proud of the 35 years of work of our socialist geological service, not only because of the creation of a raw material base for the development of the industrial power of the country, which is the main thing now, but also because through the study of the geological structure of the country we are offering a base for its study by the future generations, something not available to many other countries.

The tremendous achievements of our geological science and studies in the country earned universal recognition not only in the socialist but the capitalist countries. Currently the country's institutes are still extensively at work on scientific problems related to its geological structure and of directions aimed at the discovering of new deposits of numerous types of minerals, accomplished today under relatively more difficult conditions. Both in terms of geological studies, whose purpose is to discover and prove reserves, as well as problems of the country's geological structure, today we have great facilities through the use of the latest research methods, such as geophysics, which has developed in our country to a tremendous extent and has a powerful scientific and technical base, as well as through geochemistry, using the latest methods and proper laboratory facilities. The older methods such as the stratigraphic, structural, lithological, petrological, paleontological, chemical, and others are being steadily improved and used with the proper cadres, laboratories, and equipment.

Speaking of the cadres used in promoting the powerful development of geological studies, let us note that currently the army of geological prospectors in our country numbers from 10,000 to 12,000 workers, specialists and scientists, 2,000 to 3,000 of whom are engineering-technical personnel. Among the latter, geologists and geophysicists number over 1,000 people with higher education.

II

We already reported our achievements in the field of geological studies conducted since 1948. The purpose of this article, however, is to characterize most briefly the fuel and energy potential on the basis of extractable coal discovered in our country within that period.

Some 67 coal-bearing areas in the country were studied containing various types of deposits reflecting, to one or another extent, interesting coal-bearing features. In the overall number of areas studied in the country, broken down by individual types of coal, the picture was as follows: Deposits and basins of lignite were found in 15 areas considered of the greatest interest; deposits and basins of brown coal, in 5; deposits and basins of coal, in 8, among which the deposits of Vrushka Chuka in the Kula area, and Zeleni Grad in the Belogradchik area are considered exhausted; anthracite deposits and basins, in 3, of which the Draganitsa has been worked out.

The overall area of the studied coal-bearing areas in the country is shown in the data of Table 1.

Table 1.

(a) Площи	(b) Лигнитни въглища	(c) Кафяви въглища	(d) Черни въглища	(e) Антрацитни въглища
1. Обща площ на басейните, кв. км.	8000=100%	5896=100%	720=100%	215=100%
2. Площ на басейните, в които е проучено, кв. км	2500=30%	1202= 20%	240= 30%	20= 10%
3. Проучени площ с промишлени запаси	272= 3,5%	95,4= 1,6%	180= 30%	6,5= 3%
4. Площ за търсене на нови находища, кв. км	4250=54,5%	5024=83,5%	540= 46%	200= 93%

Key: (a) area
(b) lignite
(c) brown coal
(d) coal
(e) anthracite

1. total basin area, square kilometers
2. studied area of basins, square kilometers
3. studied areas with industrial deposits
4. area for searching of new deposits, square kilometers

On the basis of these studied areas the quantitative and qualitative deposit indicators may be determined in accordance with the data in Table 2. These data show that lignite deposits belonging to the industrial extractable category, together with forecast quantities, total 4,703,308,000 tons. Converted in terms of conventional fuel units (7,000 kilocalories), on the basis of variable and differentiated computations (from 1,300-1,600 to 2,500 kilocalories) these deposits show reserves of 914 million tons of coal in conventional fuel of categories $A+B+C_1$, and, respectively, 155 million tons for category C_2. The anticipated deposits of this type of coal, recomputed in conventional fuel, are assessed at 550 million tons.

All lignite indicators are assessed at 1,620,000,000 tons of conventional fuel.

The brown coal deposits shown in Table 2, computed on the same basis as the lignites, with a respective caloric value (3,500 kilocalories), for all categories, account for about 216 million tons of conventional fuel.

A recomputation of coal deposits as shown in Table 2, again in conven[illegible]l fuel for industrial and extractable categories, shows a total of 1,583,000,000 tons of this high-grade fuel. Adding to this indicator the coal reserves of the L-coking coal, also recomputed in terms of conventional fuel, conventions fuel reserves of such coal would total 2,200,000,000 tons. Naturally, this does not include forecasts which are not shown in Table 2 and which are currently assessed at about 600-700 million tons of conventional fuel.

(54) The Lom Basin reserves are considered nonbalance because of complex and unclarified mining-technical conditions and are not included in the overall amount of balance reserves on 1 January 1979.
(55) The geological-structural circumstances and possibilities of the basin will be determined in 1980.

Therefore, according to the data for all coal categories converted into conventional fuel, the overall coal fuel potential may be assessed at four billion tons.

The connection between our coal basins and their reserves with the individual lithologo-stratigraphic formations and their age may be characterized by the following data: Lignites are related to Pliocene formations; the brown coal is almost exclusively related to deposits from the upper Eocene. The coal basins are related to the following: Old tertiary (a single very small deposit--the Sukhostrel), deposits of the upper cretaceous (the Balkan Coal Basin), and deposits of the middle and lower Jurassic--Lias-Dogger (Ozirovo, Tuden, Slivnitsa, and others), nonindustrial deposits; the coal basins and the anthracite deposits and basins are related to deposits of the upper Carboniferous.

The biggest reserves of lignite are concentrated in the following basins: Maritsa-Iztok, Sofia, Lom, West Maritsa and Elkhovo. The relatively biggest brown coal basins are the Pernik, Bobov Dol, Pirin and Burgas. The biggest coal basin is the newly discovered Dobrudzha Basin and the drastically smaller Balkan Basin. Small industrial deposits of anthracite are found in the Svoge Basin.

The breakdown of the coal basins indicates that 13 out of 30 okrugs have coal basins and deposits and 10 okrugs have more significant industrial deposits.

In terms of origin our coal may be graded as follows:

1. All lignite basins are of the so-called platform type--fresh water swamp-lake.

2. Brown coal basins are of the swamp-lake platform type. The Burgas coal basin alone is of the limno-brackish seashore-type or mixed-type basin.

3. Virtually all anthracite basins are of the geosynclinal type--sea coastal.

Genetically, in virtually all our basins the coal was formed from humus, i.e., the residue of higher vegetation. In the Burgas Basin alone the coal is partly humus and partly humus-sapropelic.

Basic data on the chemical-technological characteristics of the coal may be found in Table 2. Naturally, in this case we are unable to provide data on the chemical structure of the inorganic part of the coal (A_c).

The overall fuel-energy coal potential computed on the basis of kilocalories is assessed at over 28 trillion kilocalories.

III

In order to describe the contribution of our geological studies conducted in recent years on the discovery of new coal deposits, we must consider, even though in its most general aspects, the description of the Dobrudzha coal basin and its deposits confirmed 11 years ago. We believe this to be the greatest discovery made so far in the area of Bulgarian geological surveys.

In the course of our search for petroleum and gas in northern Bulgaria and, particularly, in the course of the special so-called support drills made in 1963, we came across strata bearing highly caloric coal in the area between Kavarna and Balchik, at a depth of 1,300 meters. We discovered about 60 seams some of which up to 10 meters thick. Some of the seams showed coking qualities. Coal was found in the upper carbonatious deposits spread over an area of no less than 200 square kilometers.

Let us note at this point that in the course of our search for petroleum and natural gas in northern Bulgaria such drilling enabled us to discover substantial deposits of manganese in the Oligocenic deposits (in the vicinity of Obrochishte Village, Tolbukhin Okrug), as well as substantial gypsum deposits in Vidin and Vratsa okrugs. New salt deposits were discovered, unfortunately located at a great depth (about 3,200 meters) not far from Omurtag. Let us also note that dozens of mineral and hot water mineral springs were discovered throughout

northern Bulgaria and, particularly, in the coastal areas of Varna and Tolbukhin okrugs.

Following the discovery of coal in the Dobrudzha Basin deep drilling was immediately undertaken for preliminary geological surveys, as a result of which by the end of 1969 some 60 drills had been completed and a tremendous amount of geological data had been collected, processed, and presented in a special report submitted to the Central Geological Fund of the Committee for Geology. Because of the depth of the coal seams and the great complexity of the geological structure of the basin, we asked the help of highly skilled Soviet specialists who, together with Bulgarian geologists conducted the studies and drafted the report. The study determined that the basin has substantial deposits of coal assessed at 1,200,000,000 tons of high-grade coal.

We are including here the composite diagram of the geological crosscut of the basin (Figure 1). This makes it unnecessary to describe the geological structure in this article, for the column of the crosscut offers an idea of the basin's geology and the coal-bearing strata in the individual layers of the upper carbonaceous.

At this point, however, we must pay attention to one of the greatest difficulties in the development of this big coal basin: the five water-bearing strata: in the Sarmatian, Eocene, Lower Cretacious and Upper Jurassic, Lower Jurassic and the Carboniferous complex. The thickest water stratum is the Malm-Valanginian, 500-700 meters thick, whose middle area is highly cavernous, filled with water with a very high flow rate. It is this layer that presents difficulties in the drilling of shafts. The second difficulty in developing the basin is its tectonic block structure (Fig. 2).

As shown in the crosscut, the coal in the upper carbonaceous deposits is found in three conrboniferous formations. The first, identified by the geologists as the N formation consists of seven coal seams of industrial significance with estimated reserves of about 300 million tons. The coal of this formation is high-caloric (6,000-7,000 kilocalories) but has no coking qualities. In the future, as the reserves of this formation are developed, they will be used as high energy raw material. This formation is in the uppermost part of the coal deposits.

The N formation is followed by the M formation. It consists of 12 thick seams which are also low sulfuric and high-caloric coal (6,000-7,000 kilocalories), slightly more metamorphized in some of the lower carboniferous areas. One of the manifestations of this fact is that through layering such coal could yield up to 30 percent of the overall coking amount. The M formation deposits are assessed at about 900 million tons. Therefore, the overall deposits of the N and M formations total some 1.2 billion tons, provisionally classified as category C_2.

Below the M formation is the L formation containing about 41 seams which are considered by the geologists industrially unuseable because of their thinness. Studies indicated that the seams of the L series have coking qualities. Nevertheless, until last year this series was not properly considered. Let us mention in this connection, however, that one of the basic stipulations determining the

the assessment of the deposits, and is considered one of the main criteria, is the thickness of the seam.

According to both Soviet and Bulgarian methods for computing reserves through the criterion of thickness, the minimum acceptable thickness is 0.8 meters for coal and 0.7 meters for coking coal. At the time of the geological surveys international coal prices were relatively low and coal extraction had declined in virtually all countries with the exception of the USSR, Poland, the United States and China who were gradually increasing their output. The reason was that the relatively inexpensive petroleum and natural gas products, produced on a global scale, were expected to satisfy for many dozens of years ahead the needs of mankind for fuel and energy and chemical raw materials. This view and the erroneous approach adopted in assessing petroleum consumption were the reason for which no serious attention was paid to the development of the Dobrudzha Basin or to the geological processing of the L formation deposits which were not estimated. In the course of our research related to the study of the geochemical structure of the inorganic component of coal in the country (A_c), including the Dobrudzha coal basin, looking at the materials of the latter we realized that the various data related to the computation of reserves and the overall assessment of the L series suffered from a very substantial shortcoming. The detailed study of the data contained in the respective documents enabled us to determine, together with Engineer Iv. Bozhinov, with whom we cooperated, that the L formation had the potential for great reserves of coking coal. Following the study of all data and the orientational computations, we were able to definitely determine that the reserves amounted to hundreds of millions of tons. I drafted a special report to Minister Prof Stamen Stamenov and to Candidate of Geological and Mining Sciences Y. Kunev, chairman of the Committee for Geology, along with suggestions I submitted on the determination of such reserves. Both agreed, as a result of which, in accordance with my suggestions, a collective was set up which will complete the work by the end of this year. The data so far processed, however, enabled us to determine the specific reserves of the L formation. Forty of the 41 coal seams of this series showed industrial reserves. On the basis of the previous standard (seam thickness in excess of 0.7 meters) new reserves were computed in the basin totaling 630 million tons of coking coal; as the result of the standards we developed, on the basis of the updatingof the old and the new price of coking coal and the great need of such coal, its international price, in terms of coke, equals that of petroleum. Our computations show that the minimum thickness of the seam could be reduced to 0.4 meters; hence, the computations based on thicknesses ranging from 0.4 to 0.7 meters proved that the reserves could be increased by yet another 280 million tons of coking coal. In other words, the overall reserves of the Dobrudzha Basin in the N and M formations, with the added reserves of the L formation, currently totals 2.1 billion tons, 910 million of which in the L formation possess coking qualities.

The adoption of a comprehensive approach to the assessment of the studies of the Dobrudzha Basin enabled us to determine that nearly all M seams had an overall average ash content (A_c) of 22 percent, had a high content of Al_2O_3, ranging from 30 to 37 percent. Preliminary estimates show that the reserves of dialuminum trioxide may total 15-20 million tons. We report this interesting fact, for in England the flushing of coal containing such a percentage of dialuminum trioxide

for coking yields a highly effective industrial product from which the highest grade refractory materials are produced.

Another factor which makes us approach the assessment of the basin on a comprehensive basis is that the study of the waters conducted by a Soviet specialist determined that the carboniferous waters contain a high percentage of minerals, even though of a low flow, including a great deal of salt (over 100 mg per liter) and very high contents of other valuable components. The final assessment factor which must be included in the overall assessment of the basin, in our view, is the possibility to use the great flow of Valangian waters which are an excellent material for irrigation and even for human consumption.

Presenting all these facts on the Dobrudzha Basin, regarding the development of the basin's reserves, let us mention that some of the areas may have reserves of several hundred million tons. Very great attention should be paid to this matter in subsequent studies of the basin even though, on our recommendation, the Committee for Geology has already begun the study of this matter. Hence the great tasks to be implemented in the further study of the basin related to the conversion of possible and forecast categories into industrial reserves, and, particularly, the complete clarification of all problems related to the determination of the hydrogeological and engineering-geological parameters required for planning purposes.

Let us point out in conclusion that the full determination of the industrial potential of this fuel raw material related to extractable coal calls for extensive additional geological surveys involving both the conversion of assessed coal reserves into industrial reserves and forecast results into assessed reserves and the discovery of new possible reserves. In this connection extensive scientific research must be conducted since an even more accurate foundation is needed for the geological surveying to be conducted by the geology institute of the Bulgarian Academy of Sciences and the Institute of Minerals of the Committee for Geology.

The overall studies must include as a particularly major problem the technology related to the study of the determination of the types of coking coal including those requiring layering. Let us add to such studies the need for further specification of the qualitative and quantitative indicators of the dialuminum trioxide not only in the M formation but in the N and L formations as well, as well as the extraction of the valuable components contained in the waters of the carboniferous formations.

For the time being, however, the major problem is that of selecting the places for drilling the shafts. Intensive work is being done in this area by the Committee for Geology and by Minproekt together with Soviet planning organizations.

It would be desirable in the study, designing, construction, and development of the basin to use the latest technical and economic approaches, for this country does not have an abundant amount of coal even though following the discovery of the Dobrudzha Basin no other country in the Balkans has the type of coal discovered in our country.

SEPTEMBER 1980 ECONOMIC RESULTS SUMMARIZED

Prague HOSPODARSKE NOVINY in Czech 31 Oct 80 p 2

[Article from the Federal Office of Statistics: "Report on Plan Fulfillment, September 1980"]

[Text] The results achieved in the development of the national economy in September were influenced by 2 more days of available worktime than in the same month last year. Most of the basic economic indicators recorded an accelerated rate of growth that month; in certain cases there were shortcomings in meeting planned goals.

There was increased dynamism in the sales of industrial production as compared with the same month last year with respect to deliveries of consumer goods as well as deliveries for export to socialist and nonsocialist countries. Enterprise plans in all aspects of sales were surpassed. Industrial production recorded a higher rate of growth in September compared with that of January to August, whereas average daily production fell in September by 2.6 percent compared with the same month last year. Production plans of enterprises were not totally fuflilled. In construction the objectives of the state plan in overall volume and structure of building production were not fulfilled; average daily production fell by 8 percent in September compared with the same month last year. There was low fulfillment of the plan in deliveries of housing units constructed. In agriculture the harvesting of sugar beets and potatoes was delayed compared with last year. In animal production the scheduled plan for procurement of all basic animal products was met. In domestic trade the dynamism of retail sales in the main trade systems accelerated in September. Retail sales of the Nabytek [furniture] trade organization were the only ones remaining below that of last September. In foreign trade the growth rate of imports was lower than that of exports.

In centrally planned industry, enterprise plans in all aspects of sales were surpassed by the end of September. Deliveries for export to nonsocialist countries recorded overfulfillment of the plan by 3.5 points in wholesale prices and by 4.9 points in deliveries for export to socialist countries. The number of enterprises which did not meet their enterprise plans in indicators of sales trends during the period January to September was lower than for January to August 1980. In comparison with the same period last year, from the beginning of the year to the end of September the volume of deliveries for export to nonsocialist countries at all charges paid prices increased most conspicuously (by 23.2 percent). A high rate of growth was also achieved in deliveries for export to socialist countries

at all charges paid prices--110.9. With the exception of deliveries for domestic trade, the rate of growth achieved in the first 9 months in all sales trends was higher than that planned for the whole year.

In agriculture the harvesting of most of the remaining grain fields was completed and relatively good increases were attained in the crops of potatoes, sugar beets and silage corn. As of 13 October corn for silage was harvested from 94.8 percent of planned areas and potatoes from 77.6 percent of planned areas. Compared with last year, 21.6 percent of planned areas of sugar beets have been harvested. Preparation of the soil and the planting of winter crops are nearing completion. In procurement of basic animal products there was a marked increase in September of procurement of hogs for slaughter (10.7 percent or 8,000 tons more than September of last year). There was also a marked increase in the procurement of eggs over September of last year (11.8 percent) as well as fattened poultry (10.8 percent). Compared with last September the total procurement of slaughter animals including poultry was over 11,900 tons more this September, milk was 14.7 million liters more and there were 24.7 million more eggs.

In construction the low fulfillment of building production plans continued into September. The monthly schedule of building enterprise plans for construction work completed with internal resources showed an overall fulfillment of 98.8 percent. Low plan fulfillment was recorded particularly by the Silnice [highway] and Cestne Stavby [road construction] enterprises. The total volume of construction work completed with internal resources in September amounted to Kcs 7.7 billion, or 0.8 percent more than last September. However, average daily production in construction during September remained 8 percent below the level of last September. Likewise, the number of housing units delivered by contractors was lower than last September. Enterprise plans for building production were 99 percent completed in the period January to September. Almost 55 percent of building enterprises failed to meet their scheduled enterprise plans in this period. Compared with the same period last year the volume of construction work completed with internal resources increased 1.9 percent and reached over Kcs 61.7 billion. Thus 72.4 percent of the state plan for the year was completed by September. The year's planned rate of growth in construction was also lower during the 9 months in labor indicators: the number of workers and productivity of labor.

In capital construction the amount of work and deliveries completed, less Action Z [self-help] and individual efforts, (according to September estimates) came to over Kcs 92 billion in current prices during the 9 months and was 3.4 percent more than in the same period last year. From the beginning of the year until the end of September deliveries of machinery and equipment increased more rapidly (5.9 percent) than the volume of construction work (increment of 1.6 percent), even though the year's state plan assumed an opposite development in the structure of investment work and deliveries. Altogether 65.9 percent of the year's state plan for capital construction was completed by the end of September. Projects designated as mandatory tasks of the state plan achieved a higher proportion of completion with contractors' capacities concentrating on them.

In public freight transportation the September plan for transportation of goods was 99.8 percent fulfilled. The monthly railroad transportation plan was not met while CSAD [Czechoslovak Vehicular Transportation] and river shipping exceeded their planned transport objectives in September. A total of 55.1 million tons

of goods was transported in September which is 3.7 percent more than last September. From the beginning of the year to the end of September public freight transportation handled 473.4 million tons of goods, or 3.3 million tons more than was planned for this period. Total railroad loadings for the 9 months increased by 1 percent compared with the January to September period last year, and average daily loadings in freight car units increased by 0.9 percent. The average turnaround time for freight car units was 4.21 days for the January to September period, whereas the planned time was 4.06 days. Compared with the same period last year the average freight car turnaround time increased by 0.5 days.

In domestic trade the main trade systems realized Kcs 18.1 billion (in current prices) in retail sales in September. In comparison with the same month last year retail sales increased in September by 6.0 percent. From January to September retail sales came to over Kcs 154.9 billion, which is Kcs 5.1 billion more than in the same period last year. The growth rate of retail sales in the first 3 quarters is 103.4; the year's state plan for all trade systems is 102.2. Enterprise plans of growth in retail sales in the CSSR were fulfilled 101.3 percent in the 9 months, in the CSR 101.5 percent and in the SSR 100.7 percent. Planned retail sales for January to September were not met by the trade organizations Nabytek [furniture] (96.8 percent) and Odevy [clothing] (98.8 percent).

In foreign trade the rate of growth in imports slowed down in September compared with the preceding period. From the beginning of the year to the end of September total exports increased faster than the year's planned growth, both according to the territorial structure and to imports from nonsocialist countries. Imports from socialist countries recorded a lower rate of growth in the 9 months than that projected in the year's state plan. Of the year's planned objectives 72.6 percent of total exports and 69.8 percent of total imports were fulfilled by the end of September.

Personal savings account deposits increased by Kcs 344 million from 15 August to 15 September. Total deposits came to Kcs 151.6 billion as of 15 September 1980, which was Kcs 4.5 billion more than the same time a year ago.

Basic Indicators of Development of National Economy in September 1980
Increments over Comparable 1979 Period (in percent)

	Sept	Jan-Sept	State Plan[1]
Deliveries of the centrally planned industry for:			
Investment at wholesale prices	-	- 0.2	- 5.3
Domestic trade at retail prices	-	3.8	3.6
Exports to socialist countries			
--at wholesale prices	-	7.3	3.0
--at all charges paid [franko] prices	-	10.9	7.2
Exports to nonsocialist countries			
--at wholesale prices	-	6.1	4.9
--at all charges paid [franko] prices	-	23.2	15.0
Other sales for manufacturing consumption and operations at wholesale prices	-	4.3	-

	Sept	Jan-Sept	State Plan[1]
Gross industrial production	6.7	3.6	3.5
Average number of employees	0.5	0.7	0.7
Labor productivity	6.2	2.9	2.8
Construction:			
Construction work completed with internal resources	0.8	1.9	4.5
Average number of workers	- 0.5	0.0	0.4
Labor productivity	1.3	1.8	- 4.1
Housing units delivered by contracting enterprises	- 2.5	- 2.3	6.1
Procurement:			
Slaughter animals (including poultry)	7.8	0.8	0.4
Milk	3.4	6.5	1.8
Eggs	11.8	6.1	3.2
Retail trade:			
of the main trade systems	6.0	3.4	2.2[3]
Foreign trade:[2]			
Exports to socialist countries	0.3	10.5	7.2
Exports to nonsocialist countries	11.2	24.1	17.5
Imports from socialist countries	-10.2	4.9	8.5
Imports from nonsocialist countries	- 7.9	17.0	8.2

	Aug	Jan-Aug	State Plan[1]
Accomplished investment work and deliveries (less action Z [self-help projects] and individual efforts	- 1.7	4.3	2.0
including: construction work	- 3.6	3.0	6.0
plant and equipment	1.3	6.0	- 2.9
National personal earnings[5]	2.7	4.8	5.4[4]
of which: income from wages[5]	2.6	3.4	4.1
Actual cash expenditures[5]	- 4.5	4.8	3.8[4]

FOOTNOTES

1. Increments compared to actual 1979 results with the exception of industrial work indicators.

2. Data on actual results refer to actual transactions and the state plan does not include unplanned actions in the framework of cooperation, unplanned reexport trade, exchanges and conditional trade transactions, etc.

3. All trade systems.

4. Including estimated interest added to loans.

5. Data calculated on the basis of the SBCS [Czechoslovak State Bank] treasury plan.

CSSR OFFICIAL SEES URANIUM AS PRIME ENERGY SOURCE

Prague HOSPODARSKE NOVINY in Czech 31 Oct 80 p 6

[Discussion with Engr Milan Povolny, director of the Fuels and Energy Department of the CPCZ Central Committee, Engr Vladislav Novy, general director of the Czechoslovak Uranium Industry: "The Energy Future Is Called Uranium".]

[Text] There are many significant uranium deposits in CSSR territory. This uranium is of various genetic types and industrial importance and constitutes the basis of our nuclear program. This program requires a domestic raw material base capable of covering present and future needs. We discussed current progress in this area with Engr Milan Povolny, director of the Fuels and Energy Department of the CPCZ Central Committee and Engr Vladislav Novy, general director of the Czechoslovak Uranium Industry.

[Question] How would you characterize the current position of the Czechoslovak Uranium Industry?

[Povolny] Our mining industry has a long tradition, but the extraction and utilization of uranium has a much shorter history. The Czechoslovak Uranium Industry, which this year is marking the 35th year of its existence, represents an essential component of the Czechoslovak mining industry. One may briefly describe the basic fields of its activity as prospecting for and analysis of deposits of radioactive raw materials, and extraction and processing of uranium ores. In addition, it contributes to the national economy in other areas as well, for instance with the results of its technical development efforts or with its construction and assembly capacity. The development of the Czechoslovak Uranium Industry, achieved with the effective assistance of Soviet experts, and a number of the outstanding results of its efforts, both attest to the high degree of initiative of its collective.

[Novy] The history of our uranium industry begins in Jachymov, where uranium ore has been mined on a modest scale since the end of the 19th century. It was used for the production of pigments and glazes in the glass and ceramic industries, and later also as a source of radium for medicinal purposes. As we all know, uranium became an important military-strategic raw material in the course of World War II, but at the same time a way opened for uranium truly to serve mankind. The peaceful use of uranium as the principal source of atomic energy may be tied

symbolically to the start up of the first Soviet atomic power plant in Obninsk in 1954. Since that date uranium has also been a fuel for atomic power plants and I hope that in the near future it will become a fuel for atomic heating plants.

The development of the Czechoslovak Uranium Industry is closely tied to the evolution of our domestic situation and international relations since World War II. As early as 1945 the Jachymov Mines national enterprise had begun at Jachymov, from which there gradually evolved the contemporary concern, Czechoslovak Uranium Industry, with its base at Pribram. Thanks to the significant professional and material assistance of the USSR, and as a result of committed work by the people, the mining and processing of uranium ores was successfully developed at a tempo which has no parallel in our geological prospecting and mining industry. Today the Czechoslovak Uranium Industry represents a comprehensively equipped economic production unit capable of systematically and purposefully concentrating its talents and resources on the fulfillment of planned objectives. At the same time we consider it natural to present the results of our work and our collective ability to assure even additional tasks directly connected to uranium related activities.

[Povolny] I can confirm this. Our uranium miners, who are known for their exceptional performance--even for a world record in the driving of horizontal shafts--helped us to cut a potable water conduit from Zelivka to Prague: that 52-kilometer tunnel required sophisticated technological execution and is a masterpiece of the tunneler's art. They built for us the high quality basic sewer main K in Prague which has helped in the removal of sewage, and waste water generally, from important locations in Prague. And of course we are counting on their future assistance in the construction of underground tunnels for energy or water management purposes in Dalesice, Dlouhe Strane, Josefuv Dole, and elsewhere. I could also name a number of projects at which the builders and assemblers from the uranium industry have been employed successfully.

[Question] Does that mean that our uranium industry is not concerned only with the prospecting for, extraction, and processing of ore?

[Povolny] I mentioned miners and construction with respect. In connection with the development of the uranium industry it is also possible to evaluate the work of its research and development base which appeared, for practical purposes, 20 years ago, and which is today already a respected institute. In addition to the mechanization of basic mining and processing activity, there has been developed here, for instance, an automated system which has been employed very satisfactorily at the operational management level of all new electric power plant units. We are counting on a later model of this unit for the automation of the conveyor belt transportation systems in the North Bohemian lignite region and in other locations. Close cooperation with agencies responsible for energy will indicate the possibilities which are offered within our uranium industry and in the utilization of the results of its work for our national economy.

[Novy] In automation technology we are cooperating closely with the Skoda works, to which we deliver our DIAMO system for exported turn-key projects. I wish to

point out, as an example of automation technology, our approach to the resolution of our own needs and those of society. From the beginning we have been covering out automation needs, i.e. automation in the mines and processing plants. A group of "fired up" people was able to come up with a unit which exceeded the original specifications at its introduction. Because we are trying to outfit our development base and our implementational capacity, we have succeeded in significantly shortening that well known, and so frequently rightly criticized, cycle of development-production-utilization. This applies, though, for other products or contracts let as well. Again, I will mention just as examples, drilling cars and other mechanized technology for miners, processing technology, vibration technology, the equipment and technology for gunite; all of these are being used successfully not only by us, but in other fields as well. Because we develop and produce our own radiometric measuring and controlling instruments, our experts have been able to advance as far as the design and production of flaw detecting and medical betatrons. You will find mobile modules, which we first developed and produced for our geologist prospectors, today not only at various locations in the republic, but also in many other countries.

We are placing great emphasis on the close connection of operation, design, and development. If our tunneling crews achieve a peak labor productivity of about 1.5 meters per worker per shift in crosscut tunneling--as, for example, the Mladeznicka brigade of Josef Holaza did recently at the uranium mines in Pribram--then this attests without doubt to the quality of mechanization and the competence of the workers.

[Question] There is, then, very extensive activity apart from uranium. Does this not mean that there is no longer anything to do in the area of uranium?

[Novy] Definitely not. We always accord first priority to the fulfillment of our mission which is given by our very name. We have prospected our republic in relative detail, but we still cannot rule out new discoveries of uranium deposits which do not extend to the surface, or of other types than those we have mined thus far.

We have significant uranium deposits, some of which are peaking in extraction potential, while we are only just acquiring others. We must constantly improve our processing technology. At certain deposits we have reached significant depths, more than 1,700 meters, and this demands that we solve a number of complex problems connected with the ventilation and climatization of the mines. Our uranium mines, together with our own National Health Institute have always responsibly and progressively approached the solution of the hygienic and safety issues related to the mining of radioactive raw materials, and I can say without exaggeration that we are first in the world in this area.

If we want to maintain and improve these good results in the mining and processing of uranium ores we must create the corresponding technical and material base. And if something which we have developed and produced is applicable in another branch as well, then it would be a shame if we were to refuse to deliver it to other interested parties Our capacity is limited, however, and it bothers us that we

cannot satisfy a number of requests. The needs of our miners, however, will always be uppermost in our minds, and because the Czechoslovak machine tool industry produces almost no specialized machinery and equipment for them, we are forced to rely on our own sector's efforts and on imports. Therefore we are preparing to strengthen our machine tool base for the production of the specialized machinery needed for ore and uranium mining. We cannot, however, produce everything ourselves, nor must we justify this. Unfortunately, however, deliveries from our machine tool enterprises are obtainable only with great difficulty and often are not of the necessary quality. The rapid tempo of development of the uranium industry and the acquisition of new deposits characteristic of this industry have taught us to give priority to the introduction of modern technology and new forms of work. This places high demands, however, on technical and material support. We particularly need to improve cooperative and consumer-producer relationships with machine tool organizations, as well as the innovation and modernization of certain components and construction elements. Our technicians are able to design good machines and technical procedures, and our workers achieve exceptional performance with them: our responsibility is not only to direct them this way and motivate them properly, but also to assist in the creation of a corresponding organizational and material base. As we have endeavored to show, at the same time we are not closing ourselves off, but helping the national economy where we can and where we have the ability - in the drilling of underground engineering tunnels, in the transferral of knowledge, and with certain products.

[Question] How is our uranium industry helping to solve the current fuel and energy balance?

[Answer] [Povolny] The answer is connected with our directive to shift to atomic power plants in the solution to our fuel and energy balance: in the Seventh Five-Year Plan they will cover more than 40 percent of the increased production, and in later years the fuel and energy balance is expected to be resolved exclusively with the help of atomic power plants. The operation of a single block of the V1 atomic power plant saves us almost 300,000 tons of coal a month. If we have saved more than 4 million tons of coal from the beginning of operation of this power plant, that is the operation of the first and second blocks, to the end of July of this year, then this is not only a significant success, but also proof of the correctness of this path.

Our nuclear program has just begun to develop. We are planning to build, prior to 1985, nuclear power plants with roughly 3,500 megawatts of capacity, and before 1990 we will achieve an installed capacity of more than 7,000 megawatts. We have a sufficient raw materials base. On this base is an established uranium industry, which we do not doubt is capable of supplying the nuclear program with uranium. But we are also of the opinion that we can count on its assistance in selected sectors of the technical development of nuclear energy.

It is clear that we could not implement as extensive a nuclear program as we have planned without the decisive assistance of the Soviet Union. At present this assistance is in the construction of a nuclear energy capacity based on

type VVER 440 thermal reactors and later the VVER 1000, but in the 1990's we are already planning for close cooperation in the preparation for a shift to so-called fast reactors. This means that despite its abundance we must rationally manage our uranium, and in fast reactors we can gain as much energy from one ton of uranium as from 3 million tons of crude oil.

Our uranium industry has its own irreplaceable mission in the nuclear program, and the remarks of the general director, Engr Novy, that the assistance rendered to the uranium industry by our machine tool industry needs to be improved, are completely justified. The uranium industry collective often helps itself, but in a developed social division of labor this is unacceptable: certainly we cannot produce ourselves those products which are the concern of specialized factories--hydraulic units, electronic components, and the like. We must emphasize that the implementation of our intentions in nuclear energy confronts us with a number of very demanding requirements, problems, and tasks, and they must become a matter for our whole society. The comrades from energy agencies and the uranium industry will certainly not end up owing us anything.

[Novy] We are aware of this and want to help, in areas which are our responsibility as well as where we can and are able, that is in uranium-related and enriched extra-uranium activities about which we spoke.

[Question] You mentioned safety and hygiene in the uranium mines. This is a very real subject in our conversation, along with the safety of atomic power plants and preservation of the environment.

[Povolny] Unfortunately, mankind knows of the huge amount of energy liberated from the atomic nucleus in its worst form--in atomic bombs. This has naturally left justified fears regarding the use of radioactivity. However, on the other hand, these fears have called forth, as their positive consequences, the conduct of extensive research work, the introduction of systems of inspection procedures and safety measures in atomic energy so that we have today, in many ways, a more profound knowledge about the effects of radioactive materials than we have regarding the effects of the discharges from tradional coal-fired power plants. Of course it is still necessary to resolve certain problems, for instance the processing and storage of wastes from atomic power plants. Even today, however, it is possible to prove that the nuclear program will play a positive and progressive role in the preservation of the environment.

[Novy] I have already mentioned the ventilation and climatization of our very deep mines, which is a complex and demanding task not only technologically, but also in terms of the economics of mining. If I am to attempt to summarize the crucial tasks in the caring for workers in the uranium mines and processing plants, then, with the danger of oversimplification, I would mention three main areas. I would place primary emphasis on attention to the working conditions, to the environment of mining work. This includes not only ventilation, but also the development of mechanization which we have already talked about, and technical procedures, the replacement of the physical toil so typical of mining in the past. The second trend also involves the work process, and is the system of hygienic and dosimetric inspection techniques. Today we have not only the overall work

environment of the mining and processing plant areas, but also every individual, under dosimetric control. Finally I must mention the health and social services for our workers, which correspond to the difficulty of their work. Mining is basically a pillaging activity, so our first step into the natural environment is--to put it plainly--disruptive. We are trying to limit these influences as much as possible and "clean up" after ourselves. We reclaim dumps and work spaces. A system of environmental preservation measures for our North Bohemian deposit is being devised even in a state research project with the help of other professional institutes.

Attention to the workers of the uranium industry and the preservation of the environment has been the subject of the discussions of the highest party and state agencies several times. It could be said that this has been given as a foundation of our socialist system. We see in this, however, also an evaluation of the significance of our work and this is, for us, a great commitment. We have the raw materials base, the developed material technical potential, and primarily the people, who know the tasks facing them, who know the need for uranium, and who are determined to contribute to our economy not only in uranium, but by their work as a whole.

ENERGY SEMINAR URGES GREATER CONSERVATION MEASURES

East Berlin PRESSE-INFORMATIONEN in German No 124, 21 Oct 80 pp 1-14

[Excerpts from special edition, published by Press Office, Chairman, GDR Council of Ministers, on the council's Seventh Seminar on Efficient Use of Energy, held in Halle, 15 October 1980: "Experiences and Tasks in Efficient Use of Energy"]

[Excerpts] Efficient Use of Energy--Essential Element of Our Energy Policy: From the Concluding Speech by Wolfgang Rauchfuss, deputy chairman, GDR Council of Ministers; Director, Central Energy Commission

We can today note with satisfaction that our seminar made an important contribution to the preparations for the Tenth Congress of the SED. We base our statements on the fact that the analysis of the 11th and 12th conferences of the SED Central Committee in the combines, enterprises, and installations are providing strong impetus for the initiatives and activities aimed at a steady energy supply and greater material and energy savings and that the comprehensive competition in honor of the Tenth SED Congress in this field likewise produced significant results.

In his fundamental speech to the Gera party aktiv, Erich Honecker, secretary-general, SED Central Committee, particularly stressed the significance of expanding our own raw material base and consistently oriented us toward making increasing use of raw brown coal and using petroleum for the materials economy. Our discussion today proved that this demand encountered fertile ground.

Today we drafted the conclusions as to how we must proceed with a high level of action readiness, creative force, and a new pace in the economical and efficient utilization of energy as the most important factor in our proven socialist energy policy. It is precisely the rational and economical utilization of all energy sources and the increased supply and utilization of our domestic raw brown coal which constitute the firm foundations on which we will guarantee a steady energy supply for the population and the economy. This is our contribution which we will make by way of preparations for the Tenth SED Congress through our responsible work.

Being Self-Reliant

To solve the critical energy-economy and material-economy problems, our country's workers are orienting their thinking toward their own actions. This is an eloquent expression of their strong confidence in the proven policy of the party of the working class for the welfare of the people and their conviction that their vital interest are protected under that leadership.

The situation arising from the international energy and raw material development hit the GDR particularly hard because it is particular dependent on raw material and energy imports. What can we throw into the scales in order not only to master this situation but in order at all times to assure the national economic growth of our republic?

Here we have the even closer tie-in between the advantages of our socialist social system and the scientific-technological revolution;

Next we have the political organizational status and consciousness of our working class;

We have its close relationship of confidence with our party and we have the high educational level of our workers;

We have the fact that, today, thanks to the wise education policy of our party, we have more than 1.4 million cadres with college and technical school training and their number has almost doubled since the Eighth SED Party Congress.

It is of basic significance for the further successful advance on the road of the Ninth SED Party Congress that we achieve a high growth rate of production with a considerable smaller increase in energy and raw materials and fuels that are important to the national economy through a higher degree of refinement, utmost economizing, and utilization of all secondary energy, material, and raw material resources. Everybody must keep the correct yardstick in mind here. A fast production growth rate during the coming years is what we are going to have to guarantee to the extent of 90 percent through the better utilization of our raw materials, energy sources, and materials.

The reduction rates achieved so far in the specific consumption of energy, raw materials and material from an annual figure of about 3 percent must be raised to more than 5 percent. The main raw materials will during the coming years reveal a growth rate that is below one percent. In spite of increasingly complicated conditions, deliveries of raw materials from the USSR will be kept on the same level as in 1980.

Efficient and Economical Energy Utilization--Important Concerns

In our further work to secure the energy supply, we must start with the assumption that the most rational and most economical energy utilization and the elimination of any kind of energy waste are in first place throughout the country. Today, tomorrow, and in long-range terms, this is a fighting asignment for everybody. This is what we must convincingly explain to every worker, every citizen of our country, as the first prerequisite for the successful accomplishment of the energy supply during the next winter and during the coming years because everything we want to achieve calls for individual and independent thinking.

Efficient and economical handling of energy therefore is in first place because the expansion of our energy base--which we will continue to advance in the future likewise with a great effort and by using a large volume of national economy assets--is connected with growing expenditures.

Efficient and economical handling of energy is in first place because it is a question of just plain economical common sense since our discoveries tell us that the full utilization of all possibilities in this field--and the seminar brought out the magnitude of these reserves--ties up only half and in some cases even less national economic assets than would be necessary for additional expansions of the energy base.

Efficient and economical handling of energy is in first place because it is a question of respect for the work of others, for example, our miners and energy workers; because that which was created through hard work under difficult conditions must be used as carefully as possible. This is why we are guided by the idea of further stressing the careful handling of energy as an important feature of socialist attitudes toward work, as well as quickly utilizing all suggestions and ideas for economical energy use.

All managers bear a heavy responsibility for verbatim excuting the resolutions of our party and government regarding economical energy use, dating back to September of last year, and the winter directive issued by the party leadership and the government in May 1980, in the enterprises, in their LPG [agricultural producer cooperatives], their department stores--wherever energy is used--and to urge every worker, engineer, and scientist to be creative in their activities.

Exemplary Initiatives

This is what the workers of the VEB Carl Zeiss JENA Combine are doing, along with those of the VEB dkk Scharfenstein, the VEB Beierfeld Measurement Instruments Plant, the VEB Berlin Photochemical Works, and many others. Their activity is characterized by the fact that they implement the resolutions concerning energy savings and the replacement of heating oil and hard coal in their enterprise with a high degree of consistency.

In the VEB Carl Zeiss JENA Combine--which was the first combine in the republic to be recognized as a combine that works in an exemplary manner regarding energy management--all of the 13 combine enterprises have already been honored with that title. In 1980, careful measures resulted in a reduction of the heating oil utilization by one-third, amounting to about 650 tons. The use of hard coal was replaced to the extent of 100 percent through complete conversion to raw brown-screened coal in a mixture with brown coal briquettes and many combine enterprises are effectively implementing scientific-technological measures, with rising savings, moreover. In this combine, the emphasis is on the use of energy yield and the reduction of the heating and air conditioning expenditure.

One likewise however must not overlook the fact that not all enterprises are, as yet tackling the implementation of the resolutions of the party leadership and the government with the same goal-oriented attitude. The VEP Lithopone Fuerstenwalde, for example, just about promotes energy waste through insufficient management activity. For example, the workers assigned to the boiler plants and to energy-intensive drying plants are not given an incentive in the competition for economical energy utilization on the basis of technically-economically justified standards. The activities of the heating sector officer likewise were carried out very deficiently in this enterprise. This causes heavy losses during heat transfer and at the customer's end.

In our work we can start with the assumption that we have not only a high degree of consciousness and education among our working class and intelligentsia but also a well-developed management and planning establishment for energy-industry tasks, as well as a developed set of instruments for the planning and accounting of energy, which becomes considerably more effective through the resolutions aimed at the introduction of government quotas, their monthly accounting along with increased responsibility on the part of the general managers; this is also in keeping with the rising requirements for a high degree of flexibility.

1979 Primary Energy Consumption
Key: 1--Percent; 2--Raw brown coal; 3--Miscellaneous solid fuels; 4--Petroleum; 5--Natural gas; 6--Electric energy from nuclear and hydroelectric power plants.

Clear Concepts

The resolutions of the SED Central Committee Political Bureau and the Council of Ministers of September of this year regarding the comprehensive implementation of efficient energy utilization in 1981-1985 are of basic significance. The important thing now is to make sure that the ministers and general managers will draft their own concepts for the implementation of efficient energy utilization, starting with a thorough analysis of their sphere of responsibility, and that they will make that a part of their plan.

The most important thing here is to bring about agreement among goals in the fields of science and technology, rationalization and investments with the existing energy source quotas both in terms of the sum total of energy consumption and regarding the specific energy source. Only those concepts are useful to use in which the energy rationalization targets agree with the energy sources contained on our balance sheets. That starts in 1981.

Here we must prove that the assignment given by SED Central Committee Secretary-General Erich Honecker--once again formulated in the address to the Gera party aktiv--was correctly understood everywhere. So, let us fight for the utilization of the energy yield, let us fight for a reduction in energy consumption and for higher production targets with less energy--that is what this is all about.

The conference proved that we have made good headway since the sixth seminar in increasing the effectiveness of energy utilization in the national economy. At the same time we were able to see that we have the strength to attain the high goals for the years 1981-1985. The important thing now is to throw this ability into the scales by way of preparation of the SED's Tenth Party Congress and that we always start with the assumption that questions of energy and material savings are vital issues in our national economy.

Nobody must expect the situation in this field to become simpler and nobody must expect anybody to relieve him of his responsibility. Efficient energy utilization remains the very nucleus of our energy policy and a main factor in increasing the effectiveness of the national economy.

Ensure Economical and Efficient Use of Energy: From Speech by State Secretary Heinz Ziergiebel, Chief, Working Group on Efficient Energy Use, GDR Council of Ministers

[Text] At the 11th Conference of the SED Central Committee at the end of 1979 SED Central Committee Secretary-General Erich Honecker already observed that a new situation has arisen for the GDR which above all will have profound consequences regarding the output, importing, and utilization of all energy sources. This situation estimate was confirmed throughout 1980. The situation on the international energy source market has become more critical above all because the external conditions for raw material procurement and especially for energy sources such as petroleum, hard coal, and coke, which we must import most of all, have been drastically aggravated.

The party leadership and the government have adopted fundamental resolutions in order--through the most economical and efficient possible utilization of fuels and energy, primarily involving imported energy sources, and through the elimination of any waste--to create the most essential conditions for a steady energy supply in the GDR. This is the very core of our continuing energy policy; that is what the secure energy supply depends on primarily in connection with the continuation of the successful

economic and social policy of the Ninth Party Congress during the coming winter and the next several years.

As Erich Honecker noted in his fundamental speech to the Gera party aktiv conference, the important thing is to achieve the required increase in performance, the supply of more and better final products for the supply of the population, for the national economy, and for exports with a quantity of energy sources and primary raw materials "which will remain the same or which will increase only slightly. Successfully accomplishing this task is a vital issue in the truest sense of the word for the DGR national economy."

Visible Results and High Demands

A high rate of national economic growth was achieved for the first time in the GDR in 1980 without a rising energy utilization. Combines, such as, VEB LEUNA-WERKE "Walter Ulbricht," Carl Zeiss JENA, the "Wilhelm Pieck" Schwarza Chemical Fiber Combine, Shipbuilding, GISAG, Cotton, or the "7 October" Machine-Tool Combine, the Photochemical Combine and others in 1980 are guaranteeing considerable output increases with less or the same energy than during the preceding year. Today they are already tapping those reserves through the elimination of any kind of energy waste and consistent socialist rationalization with their own resources, as is in keeping with the requirements for the eighties.

Since the Eighth Party Congress, the primary energy expenditure per unit of industrial growth output has been reduced by 25 percent. The benefits deriving from energy rationalization in our enterprises over the past 9 years amounts to about 90 million tons in terms of raw brown coal. The directive of the SED Central Committee Political Bureau and Council of Ministers concerning the comprehensive implementation of efficient energy utilization during the 1981-1985 five-year plan now starts with the idea of saving more than twice the energy than during this five-year plan through rationalization, in the year 1985 as compared to 1980, on the scale of the national economy as a whole.

These targets are above all a challenge to science and technology. Accelerated rationalization of the production processes and the development of new energy-saving technologies and products with top-grade international values are decisive prerequisites in order to guarantee dynamic economic growth with a small energy increase in the long run. The most economical and the most rational utilization of energy is a national economic effectiveness factor of the first order. It demands considerable expenditures which however are at least by one half lower and in many cases even lower than that, than would be required for the expansion of our energy base and for the procurement of energy from imports--something for which we continue to require signficant national economic assets, at any rate, more than has been used for this purpose so far.

Use More Raw Brown Coal

The drastic change in the conditions connected with the import of energy sources compellingly demands a fast increase in the output of raw brown coal and its maximum utilization in the economy and in the social sector.

Heating oil must be released as fuel to a hitherto unknown degree because the stepped-up materials-economy utilization of petroleum and imported natural gas represents a decisive foundation for the raw material supply of the GDR national economy during the coming year. We start with the assumption that raw brown coal--in spite of increasingly unfavorable conditions regarding its extraction--is and remains by far the most effective energy source for the GDR in terms of its national economy. Looking at present-day prices alone, we can see that the social expenditure for one heating unit based on natural gas is four times greater and in the case of heating oil even eight times greater than in the case of raw brown coal. The increasing difficulties, which are undoubtedly connected with the use of raw brown coal, must be mastered in terms of the national economy and that is proved by the practical results; but the consequences arising otherwise from growing import burdens cannot be brought under control.

The initiatives triggered as a result of the resolutions of the party and government concerning the economical and efficient utilization of energy of September 1979 and the directive on fuel and energy supply during the coming winter semesters as well as the introduction of government quotas for energy supply enabled us during the last year to make most effective progress in our energy savings effort. Careful handling of electrical energy and heat, elimination of overheating and unnecessary illumination resulted in savings of 6-8 percent for electric energy and heat. That helped us save considerable quantities of heating oil, hard coal, and brown coal briquettes.

It is particularly important here to make sure that we achieve the output increase in industrial commodity production, almost without any increase in energy utilization, by the end of September. The specific electric energy consumption for industrial commodity production dropped by 6.2 percent compared to the preceding year. For the first time, likewise, we noted a considerable decline in energy consumption during that year in the communal sector; that is an expression of successful work, above all by the councils of the bezirks and the kreises and their energy committees which are increasingly developing into effective agencies working on the implementation of our socialist energy policy.

Compliance With Government Quotas

Although we can be satisfied with what we have achieved, we must not overlook the fact that--judging by the new requirements--initial steps were taken although much remains yet to be done. The past months tell us that the consistent implementation of resolutions concerning work with government quotas holds a key position. Government energy consumption quotas

constitute minimum requirements regarding the efficient utilization of energy but at the same time are the maximum permissible limit for energy consumption. They call for high quality in energy consumption norms. Government quota, energy supply contract, and cost planning must form a unit here. If the government quotas are exceeded, then government penalties will be collected for any additional consumption in the amount of ten times the price. The responsibility of the general managers of the combines for this task was considerably increased. We can say today with certainty that this resolution proved itself fully.

Our past work however also shows that much remains to be done in order everywhere to implement the required high level in connection with planning and accounting the energy consumption as well as regarding order and discipline in handling energy. At the end of August, there were still ten combines that exceeded the planned energy consumption figures.

Presently, about 80 percent of the energy utilization in conversion plants in industry and barely 50 percent of the energy consumption in practical application plants are being investigated by means of processed analyses. Nevertheless, their results have not yet been adequately transposed into technically-economically justified energy consumption norms and rationalization measures. Thus, the energy consumption in the combines of the ministries of ore mining, metallurgy and potash, of the chemical industry, as well as of coal and energy, are being planned to the extent of more than two-thirds with technically-economically justified norms while that share in the combines of the ministries of the metal-working industry, of electrotechnology and electronics, of the glass and ceramics industry, as well as the light industry comes to less than 30 percent.

Record Achievements in Science and Technology Indispensable

In order to develop the rational use of energy into the decisive factor of our energy policy in the long run, we must today absolutely have record achievements in research and development so that we may--in the planning and design of products, systems, methods, and building structures--quickly attain scientific-technical top-level standards in energy consumption, in the weight-output ratio, in the waste statistics, and in other important quality characteristics.

The drafting of 550 energy consumption norms, which are contained in 43 GDR standards, helped us in a series of products to achieve international top values for energy consumption. That involves the development of a new generation of induction heat systems at the VEB Locomotive Construction Combine, the "Hans Beimler" Electrotechnical Works at Hennigsdorf, where the specific electric energy consumption was reduced by one-fifth particularly through the use of static frequencies changers and where they managed to catch up with scientific-technical top-level standards.

The analysis of the valid energy consumption norms however also reveals that, in the case of several standards, the energy consumption achieved

is partly as much as 50 percent below the value of the confirmed standards so that this particular standard no longer has any stimulating effect.

Research and development must make the decisive contribution to the most efficient development of technological processes in our economy and the development of new results and methods with international top-level figures in energy consumption in order to attain and help determine top-level positions in the main directions of energy conversion and application. This is the critical point when it comes to asserting the most efficient utilization of energy, during the coming five-year plan and far beyond that, as the main pillar of the country's energy policy.

In order to manage and control the efficient utilization of energy more effectively with the help of the plan, the most important measures in the field of science and technology, of socialist rationalization as well as investments will, starting in 1981, be spelled out along with the state plan and central planning will be organized by combines. With the confirmation of the energy plan and the plan of rational energy utilization measures as a part of the enterprise plan by the general managers and plant managers starting in 1981, the possibilities of influencing the implementation of efficient energy utilization through the plan will be considerably increased.

Many combines are aiming at the correct goals. The VEB Carl Zeiss JENA Combine, in agreement with the high pledges spelled out in the letter to SED Central Committee Secretary-General Erich Honecker, guarantee an increase in 1981 industrial commodity output to a figure of 111.3 percent coupled with a decline of energy consumption down to 98.8 percent. The Wilhelm Pieck VEB Chemical Fiber Combine in Schwarza is topping the predetermined target for energy rationalization for example by energentically continuing the successfully begun utilization of energy yields which so far has resulted in an annual energy cost reduction; with the help of the 1981 plan, they want to reduce the energy requirement to 96.2 percent as compared to 1980. On the other hand, there are still combines and enterprises which do not meet the predetermined rationalization targets.

Better Utilization of Manifold Reserves

Critical points consist of the processes of energy conversion and technological heat and drying processes, including energy yield utilization. Here we can earn two-thirds of the savings potential, based on our calculations for the next several years, with a particularly favorable ratio between expenditure and benefits.

A group of experts have discovered that improved plant organization and waste heat utilization as well as the employment of modern burners, furnaces, and fire-proof material, in about 21,000 industrial furnaces, above all in metallurgy and chemistry, in the metal-working industry, the construction materials industry, and the glass and ceramics industry, will make it possible to tap reserves corresponding to a raw brown coal equivalent of 28 million tons, including 7 million tons alone through better plant

management and utilization of available BMSR [industrial measuring, control, and regulating technology] equipment. In these high-temperature processes, we use above all heating oil, gas, coke, brown coal briquettes, and electrical energy. The average rationalization expenditure amounts to only one-sixth of the funds otherwise needed for energy source procurement. And we must add that heat treatment in such furnaces, in keeping with quality requirements, decisively influences the quality of GDR products.

The are great possibilities for waste heat utilization, above all waste gas heat, in the temperature range between 400 and 1,200° C. Only a part of the fuel-burning industrial furnaces is equipped with air preheaters. Possible air preheating of up to 600° C reduces the energy requirements by 30 percent.

The consistent utilization of energy yields as the safest energy source, because it is present in each plant itself, above all calls for corresponding preparations in the combines and enterprises. The study however shows that there are still backlogs in the preparation and utilization of the energy yields at the plants.

Energy Savings During Construction Work

Energy-saving construction activities, efficient handling of energy in room heating--these are of great importance to the energy economy of the GDR. In the meantime, energy utilization for space heating has risen to more than 36 percent of the utility energy consumption. The Seventh Construction Conference of the SED Central Committee and the Council of Ministers directed the workers in the construction industry quickly to create a scientific head start in order to reduce the energy expenditure for new buildings and structures to be modernized by at least one-third by the year 1985.

The improvement in the quality of work in the board factories--as demanded in the winter directive--takes first place when it comes to saving energy in construction work. But here we often have energy losses of up to 20 percent per construction project. This is an extraordinary loss to the national economy if we keep in mind that buildings which contain quality shortcomings will unnecessarily burden our energy inventory for many decades to come. Subsquent repair work is expensive, in most cases it is not possible, and it does not produce the same anticipated effects as the proper kind of construction work would, if it were done correctly from the beginning.

Good lessons have been learned in the Schwerin and Karl-Marx-Stadt housing construction combines with respect to quality control and the implementation of government heat consumption norms. In Schwerin, the bezirk energy committee, the energy combine and the housing construction combine--through the rational development of the WBS-70 [Housing Construction Standard?] type--since 1976 reduced the heat requirement per apartment unit by one quarter and thus stayed within the norm. Quality control, better heat

insulation along gable walls as well as in the ground floor and the gable ceiling and more effective regulator equipment were important factors here. But not everybody is working in this way.

Economical energy utilization for space heating also calls for compliance with the adopted room temperatures. That must be ensured everywhere. Measurement and control of temperatures, expert regulation systems, use of precise operating curves, disciplined compliance with heating phases are just as indispensable for this purpose as the guarantee of the proper condition of the heating plants, including the proper functioning of the regulating valves [registers] on heating units. It is once again necessary to have all enterprises, government agencies, and public institutions investigate whether all prerequisites exist for proper space heating coupled with strict economy. This is important above all also for the health and well being of our citizens.

Reducing the Transportation Expenses

Fifteen percent of the national economy's energy requirements are taken up for transportation processes. Carburetor and diesel fuel are used mostly for this purpose. The most important thing here is the reduction of the transportation expenditure as such, the most efficient possible development of transportation, including the transportation structure, in order to use fuels as economically as possible. In 1980, considerable results were achieved as a result of the implementation of the resolutions. The transportation services were increased by 4.3 percent by the end of August and the use of diesel fuel was reduced by 4.4 percent compared to the same period of time the year before. This was possible above all because highway transportation was shifted to the railroads and to inland shipping.

But there are still great possibilities for savings in motor transport. In more than 3,000 inspected vehicles, technical and organizational shortcomings, exceeding the speed limit, and similar observations were made regarding 60 percent of the trucks. Among the trucks inspected, more than 500 were being driven without trailers.

It is also important to compare the same vehicle types with respect to fuel consumption. For example, we detect differences in vehicles of the same type in public and plant traffic in Halle and Dresden bezirks, amounting to as much as 45 percent; there is no justification whatsoever for that. Results of dispatcher stations which work in an exemplary fashion all show that--compared to the currently applicable guideline catalogue of the Ministry of Transportation--we are indeed achieving savings of up to 1.5 liter per 100 kilometers below the required level for passenger cars. The time has come to orient this standard catalogue to a greater extent by the optimum values actually attained.

1979 GDR Energy Flow Chart. Key: 1--Primary energy; 2--Utilization for energy conversion; 3--Energy supply from conversion; 4--Direct utilization; 5--Inventory change and exports; 6--Conversion losses; 7--Utility energy supply; 8--Application [utilization] losses; 9--Useful energy; 10--Utilization in materials industry [economy].

Growing Number of Exemplary Enterprises

The struggle for the title "Enterprise Working in an Exemplary Fashion in the Energy Industry" holds a considerable place in the endeavor to step up energy savings. More than 600 enterprises and installations have so far been able to win this title and they use 45 percent of industry's utilization energy. Starting in 1980, this title will also be awarded to cities and communities through the director of the Central Energy Commission for good results in energy-management work.

But the criteria for the attainment of this title will be pegged higher. Complying with government energy saving quotas, meeting rising production assignments with the same or lesser energy quantity, exemplary work with norms and high quality of products in terms of energy--these will carry greater weight in the award of these titles.

We will likewise not deviate from the basic principle to the effect that every enterprise which works in an exemplary fashion in the energy department must pass on the good lessons it learned within the branch and in the territory, the way in which, in Dresden Bezirk, in each kreis, an enterprise doing exemplary work in the energy department is doing active work as consultation base. We are concerned here with enterprises that do far more exemplary work in the energy department. We need optimum achievements not only in individual cases but across the board.

The development of enterprises and installations which work in an exemplary fashion in the energy department in community and social installations is still in its beginnings. Here at any rate we still take up 25 percent of the GDR's utility energy. Through the development of pilot enterprises for the maintenance and care of heating plants and BMSR equipment as well as burner adjustment in the bezirks and kreises, we must give even more effective support to the smaller enterprises and installations in these sectors in terms of the proper operations management and repair of their systems.

The most economical and the most rational possible energy utilization is of the utmost national economic and political significance and reveals a long-term and strategic character. This is something which the managers must more than ever before address themselves to. Let us be guided by past experience to the effect that knowledge regarding the interrelationships, regarding the national economic requirements on the part of every citizen, with a high level of technical knowledge, and at every work station, constitute those prerequisites from which will grow the kind of creative action, ingenuity, and high action readiness which we need.

Domestic Raw Brown Coal--Most Important Energy Source: From Speech by Wolfgang Mitzinger, Minister for Coal and Energy

[Text] Our concept for meeting the growing energy requirement of socialist society in the GDR starts with the consistent implementation of efficient energy utilization as well as the rapid increase in the output of raw brown coal. These new requirements also increasingly determine the action of the miners and energy workers in the combines, enterprises, and scientific installations of the coal and energy industry.

Considering everything that has to be done in the very near future, we must basically start with the idea that we must never and nowhere allow any kind of smug complacency. The conditions for a reliable energy supply are subjected to a high degree of dynamics. Something that is still sufficient today will no longer meet requirements tomorrow because the influence springing from the international market constantly confront us with new requirements which call for new decisions everyday regarding a reliable energy supply and a rapid response. There is only one way for us and that way is the increased use of raw brown coal.

Larger-Scale Substitution

The basic issue here is to meet the energy requirements to a much greater degree than so far planned on the basis of raw brown coal instead of hard coal and coke. Here is what that means: on the one hand, we must make available, for the producers, during the fourth quarter of 1980, solid fuels from our own production above and beyond the plan targets and above and beyond the competition pledges given so far. On the other hand, all energy consumers must, in addition to the tasks spelled out so far, regarding the substitution of heating oil and assorted energy hard coal, carry out additional measures with the support of the energy combines and the energy committees in the bezirks and kreises regarding the direct utilization of raw brown coal and, in special cases, also in case of admixtures of briquettes.

The main issue now is to make sure that, in all consumer areas, the use of raw brown coal will serve to release hard coal, coke, and briquettes without any reservations and that no time delay will be permitted here. The decisive thing thus is to make sure that the raw coal supply in each of the enterprises designated will actually be used in each installation specified.

There are already many enterprise collectives which are briskly using raw brown coal and which show us how the problems of raw brown [coal] extraction and screening-coal utilization can be mastered. These are enterprises in which this process is being directed correctly in political terms, enterprises where they long ago stopped discussing all of the "ifs" and "buts" and where they are instead tackling the tasks specifically. That was clearly brought out during a discussion in Leipzig on 17 September.

New Ways Opened Up

At the Erfurt-Rudisleben Chemical Systems Construction VEB, the swing-thrust grates in small water boilers were converted to raw brown coal by means of a change in the grate charging, the extension of the return plate, the increase in the swing frequency and the adjustment of the dumping height to the use of raw brown extraction and screening coal. Here they achieved almost the same performance parameters as during briquette firing. This system is now being carried out according to plan and the briquette quota was returned.

In Leipzig it was demonstrated just as convincingly that the use of screening coal on flat grates with stoker or manual charging is possible during heating-up with briquettes if the corresponding performance parameters are guaranteed. Here again, the necessary measures were documented in the information material released by the "Brown Coal Briquette Substitution through Raw Brown Coal" study group. The Leipzig Colored Yarn Works VEB were designated as consultation base.

The Harzer Works in Blankenburg successfully converted their steam generators from coke to screening coal and briquette firing. Measures designed

to implement the admixture of raw brown coal for briquette-fired articulated boilers in the various versions were demonstrated just as clearly. This enterprise engaged in another initiative. A suspension grate with secondary air supply was developed and cleared for production for the GK 20 articulated boiler which in the past achieved its planned performance parameters only when coke was used; it now guarantees the use of brown coal briquettes with full heat yields. This grate will be sold during the fourth quarter of this year through the Household Appliances Wholesale Company in related retail stores. The initiative displayed by the personnel force at the Harzer Works in Blankenburg will help us better solve problems of coke supply for social installations and the population. This initiative must now be continued for the use of screened coal.

We are naturally not overlooking the fact that the measures adopted may be connected with more labor on the part of operating personnel and, to a certain extent, a decline in boiler output. In many cases we run into the problem of storage capacity, the ash yield is greater and we are also going to run into other problems. It is therefore all the more necessary to provide strict management for the newly determined use of solid fuels in political and technical-organizational terms through the general managers of the combines, the council chairmen, and the plant managers, down to the last boilerman and uncompromisingly to implement this measure coupled with the full discharge of the individual responsibility of the energy users.

Spread Good Experiences

I would like briefly to summarize the good lessons we have learned. First of all it is necessary to make sure that the managers will personally organize this substitution process and that the implementation of the resolutions adopted in this connection, as well as the central directives, will be strictly supervised.

Second, the best results are achieved wherever--on the basis of fundamental decisions of our party and government regarding fuel utilization--a broad mass initiative of the workers is organized in pursuit of the most economical utilization of energy sources spelled out in terms of quotas. The important thing here is to make sure that our own reserves will be tapped for conversion and for reconstruction of boiler plants for the new fuel and that we explain to the boilermen why we are establishing and must establish new tasks for them likewise.

Third, our past experience shows us that the implementation of the central basic government guideline for fuel utilization calls for effective support from the local councils and their energy committee. Starting with the organization of territorial storage and transportation processes, continuing by rigid control of quota implementation and especially raw coal utilization, all the way to passing on experiences and lessons learned--all of these are tasks which can be organized most effectively in the territories.

Fourth and not last, it is also important to organize bezirk initiatives to tap local fuel reserves. For example, the Schwerin Bezirk energy committe made determinations regarding the utilization of broken wood which is no longer technologically useful, of wood residues and stumps, instead of brown coal briquettes. We do not consider this to be an emergency solution. The utilization of this kind of wood and of local peat deposits must be developed into a lasting factor, especially for the local fuel supply of agriculture and forestry.

It is therefore necessary to make sure that the bezirk and kreis energy committees, in cooperation with the agriculture and forestry departments, will quickly prepare a survey of these reserves, organize their utilization, and consider the use of such local energy resources in dimensioning the fuel quotas. Suggestions from citizens confirm again and again that many unused reserves are still present in this field.

Only through a significant increase in the supply of fuels and energy from domestic resources, through the complete elimination of energy waste in all sectors of social life, and through the increased direct utilization of raw brown coal instead of heating oil, hard coal, coal, coke, and briquettes will it be possible for us to accomplish the tasks facing us.

ENERGY CONSERVATION ACHIEVEMENTS REVIEWED, PROSPECTS OUTLINED

East Berlin EINHEIT in German Vol 35 No 10, Oct 80 signed to press 11 Sep 80
pp 985-987

[Commentary by Wolfgang Rauchfuss, member, SED Central Committee; deputy chairman, GDR Council of Ministers; minister for materials management: "How Is Energy Conservation Progressing?"]

[Text] Considerable progress has been made in the GDR in recent years in the implementation of efficient energy utilization and in the struggle for a high savings rate in connection with energy consumption on the basis of the resolutions of the Eighth and Ninth SED party congresses. In 1976-1979, for example, when we had an average annual primary energy consumption increase of only about 2.5 percent, we were able to achieve more than twice as high industrial commodity output growth rates. This is a considerable achievement even on an international scale.

The reduction rates for electric energy and utility energy intensity, which were given to the economy as requirements, were attained and partly topped. Accounting for energy consumption during the first half of 1980 shows an increase in primary energy consumption amounting to less than one percent coupled with an industrial commodity output growth rate of 6.1 percent. This proves again that the resolutions of the party and the government regarding efficient energy utilization and elimination of any energy waste are becoming increasingly effective.

The point of departure in the management and planning of energy-industry development in the GDR and for all other sectors of the national economy must be the observation by SED Central Committee Secretary-General Comrade Erich Honecker to the effect that both the starting positions and the essential conditions for future dynamic economic growth differ at the start of the eighties from the situation during the past decade. The GDR today faces two major tasks in the field of the energy industry.

First of all, it is necessary to guarantee dynamic economic growth during the 1981-1985 five-year plan with a considerably lower increase in annual primary energy consumption. This means that efficient energy utilization during the eighties must make a far greater contribution to guaranteeing the fuel and energy inventory than during the past decade.

Second, the increase in primary energy during that period of time must be achieved only on the basis of domestic raw brown coal--which is still our most important energy source--and, to a limited extent, by means of an increase in nuclear energy, coupled with simultaneous substitution of heating oil and assorted energy hard coal. To attain this goal it is necessary to produce the required equipment, such as steam generators, coaling and ash removal plants, etc., and to erect the necessary

plants. These tasks create maximum requirements for science and technology and demand comprehensive investments.

The September 1979 resolution of the SED Central Committee Secretariat and the GDR Council of Ministers, entitled "On Efficient Utilization and Savings of Electrical Energy, Heat, Furnace and Engine Fuels as Well as the Elimination of any Waste in 1979," ushered in a new phase in the implementation of efficient energy utilization and economical employment of energy. Manifold initiatives were thus triggered in the combines, enterprises, and collectives. Many citizens submitted suggestions and provided hints as to economical and efficient energy use. Comprehensive measures for the elimination of energy waste and the tapping of reserves were taken in the enterprises of industry, the construction and transportation industries, agriculture, forestry, and the food industry, commerce, as well as educational installations, cultural facilities, and other sectors.

As a result, it was possible to relieve the electric energy and heat situations during the 1979-1980 winter semester by 6-8 percent; that meant that we were able to save considerable quantities of heating oil, gas, and solid fuels. That was a considerable contribution to steady energy supply in the GDR in the winter of 1979-1980.

To guarantee a better system and discipline connected with the economical utilization of energy in the economy, government quotas were issued in 1980 for the consumption of energy sources and the responsibility of the general managers of the combines for planning and accounting of energy sources--especially for the drafting and application of scientifically justified energy consumption norms--was increased. In this way we also better guaranteed uniform responsibility for production and energy consumption while at the same time we created better prerequisites for complex energy-industry work in the combines--the sort of thing that proves itself wherever we employ well-trained management personnel to accomplish energy-industry tasks and wherever we do not tolerate any narrow parochial approach to the work that has to be done. The lessons learned by such combines as the "Walter Ulbricht" Leuna Works--where the workers in socialist competition set themselves the target of guaranteeing output increase in 1980 already with less energy--should be applied in all combines and enterprises. The results and experiences of the workers at Leuna as well as the approximately 600 enterprises which in the meantime have received awards for exemplary energy-industry work constitute a good foundation for further successful energy-industry rationalization in all enterprises. The important thing is to help and support all collectives which have set themselves this task.

Through a combined effort with the ministries and combines, we drafted a "Concept for the Comprehensive Implementation of Rational Energy Use During the 1981-1985 Five-Year Plan." It starts with the idea that we must accomplish growing production tasks in many branches of the economy with the same energy quantities or with reduced energy utilization and at the same time replace imported energy sources--especially heating oil and assorted energy hard coal--with raw brown coal.

The concept comes up with specific assignments for the rationalization of the most important energy-industry processes, such as electric energy generation and

transmission, heat energy generation and transmission, space heating, technological heating processes, transportation processes, as well as electric energy consumption during the most important processes. High targets have been established for each combine regarding energy rationalization and the energy effects to be attained have been spelled out. Each combine and each enterprise now faces the task of drafting its own rationalization concept which starts with the idea that the production increase must lastingly be guaranteed with the energy quantity used so far or with a smaller quantity. Today, questions of energy savings of a long-term and strategic nature. They demand long-term concepts, they must be thoroughly discussed in the collective and they demand clear decisions.

What should we concentrate our efforts on primarily in tapping energy reserves?

The drafting and consistent application of technically-economically justified energy consumption standards are of special importance. Here we still have backlogs and delays in connection with various products which must be eliminated quickly.

In implementing the enterprise rationalization concepts--which are supposed to concentrate, among other things, on the insulation of heat-conducting lines and fixtures, the reduction of condensate and compressed-air losses, the utilization of energy yield as such, especially from heat processes--we must start with the increased use of our own, in-house capacities, especially the rationalization equipment construction and building construction departments. The energy-industry targets for the development of new products, processes, and technologies must relentlessly be measured against international top-level standards. That is the only way we can make sure that the prerequisites for the reduction of specific energy consumption will be created along with the new product or method. We are helped in this effort if we apply even stricter criteria in the confirmation of energy consumption norms and specifications, if especially the planners, designers, and technologists are involved even more effectively into energy-industry work and are urged to display ingenuity in their work.

We still suffer considerable energy losses due to incorrect operations management, especially effective equipment and maintenance of MSR [measuring, control, and regulating technology] installations and inadequate skill levels on the part of operating personnel. The implementation of economical energy consumption inevitably demands an exactly functioning MSR equipment unit and a high level of know how among operating personnel. The requirement for this is the necessary equipment of the systems with MSR installations and constant and above all system-related skill training for operating personnel. The unity of knowledge, ability, and constructive action on the part of the workers who handle these systems with a high energy utilization rate is of extraordinary importance for efficient energy use.

The exact accounting of energy consumption both for individual subsystems and for enterprise divisions and combines constitutes an important foundation for the implementation of government energy policy and energy savings. A particular critical main point here involves compliance with technically-economically justified energy consumption standards and the derived government quotas for energy consumption. Monthly accounting of energy consumption must become a constant management task of the enterprises and combines--not only if energy consumption has been exceeded with penalties amounting to ten times the price.

It is in the interest of all of us if the objectives of socialist competition include, in the enterprises and combines, the technically-economically justified energy consumption norms, measures aimed at the substitution of high-grade imported energy sources, scientific-technical objectives regarding the development of new products, the accomplishment of selected rationalization measures by the required deadline and with the required quality, and compliance with government quotas. The important thing here is to assign accountable tasks to the teams, plant divisions, and enterprise personnel forces and to organize their specific accounting.

To increase social influence and to guarantee the democratic cooperation of the workers in the combines and enterprises we have formed energy aktivs. It is their task above all to discuss the monthly results of the accounting of government quotas for energy consumption and the implementation of the "Plan of Measures for Efficient Energy Use." The emphasis here is on complying with government quotas and using less than specified in the government quotas as well as supervision over the implementation of all points in the plan of measures along with a check on the effects regarding specific and absolute energy consumption. It is a matter of energy policy to come to grips with the implementation of important innovator proposals regarding efficient energy use and to support their rapid practical implementation. The high demands of the eighties regarding economical energy use and the significant output increase in the field of the energy economy as a whole call for effective work by management personnel with a high level of political and technical knowledge. At this time, available training capacities are not being fully utilized at all colleges and technical schools although the enterprises in some cases are having shortages of cadres, especially for the management of technological heat processes. In the future the enterprises and combines should develop greater initiatives regarding the training and detached duty assignments primarily of young skilled workers and above all to the Zittau Engineering College, the Freiberg Mining Academy, and the Markkleeberg Technical School. It is important to make sure that all universities, colleges, and technical schools fully utilize the possibilities for the basic and advanced training of personnel in fields of science in accordance with rising requirements.

The implementation of efficient and economical energy use also confronts the public with new and higher requirements. Critical main points here are the rapid and effective popularization of the experiences of the best workers, the imparting of new discoveries and insights into the energy policy of the GDR to all citizens of the country, combined with persuading people consciously to cooperate toward economical energy use in the individual sector. The dissemination of interesting and convincing examples of efficient energy utilization in the economy and the transmission of specific recommendations aimed at preventing energy losses at home must be continued with even higher quality in the press, on radio and television so that "energy saving" will be increasingly upbeat in the GDR as a result of the conscious cooperation of its citizens.

ECONOMIC REFORM ON HUNGARIAN MODEL CONSIDERED INADVISABLE

Warsaw KURIER POLSKI in Polish 19-21 Sep 80 p 3

[Interview with Dr Jan Mujzel of the Institute of Planning, Planning Commission of the Council of Ministers, by Jerzy Jagodzinski and Marek Rapacki]

[Text] "An indispensable factor for improving our economic situation and for a continual increase in management efficiency is the execution of broad changes in our methods of planning and management of the national economy. We are in the process of preparing a plan of comprehensive reform in this area." The above words come from a Sejm expose delivered by Premier Jozef Pinkowski on 5 September. The KURIER requested an interview on this subject with the distinguished specialist on problems of economic systems, Dr Jan Jujzel of the Institute of Planning, Planning Commission of the Council of Ministers.

[Question] Professor, the study of Polish economics is facing new, difficult, but exciting tasks...

[Answer] Often a little too much is expected from scholarly study. The study of the workings of the socialist economy is still in a state of infancy. Moreover, there are many aspects and problems of the system of operation of an economy about which research in general cannot make unequivocal judgments. These are those problems about which scholarly positions cannot help but include a value judgment. And it is known that value judgments belong to the category of subjective opinions. Consequently, it is only natural that the views of economists are diverse on these questions.

Our limited knowledge and the controversiality of views have always stood in the way of systems changes to a certain degree. The politicians faced decisions which were attended by many basic uncertainties, not only from an economic viewpoint, but also from a sociopolitical point of view.

[Question] But people have a right to ask why systems changes have been discussed for 25 years without visible results, don't they?

[Answer] Indeed, society is not happy with the operation of the traditional system of planned economy which was instituted in Poland at the end of the 1940's

and the beginning of the 1950's. This system is sharply criticized in circles of professional economists and practitioners as well. Despite this we have not succeeded in extricating the economy from its logic. Two major attempts were made in the second half of the 1950's and in the first half of the 1970's, several lesser attempts were made in the interim. Unfortunately all of these were fundamental attributes of the traditional system.

[Question] And now we are embarking on a third great attempt?

[Answer] Let us say we would like to believe that we are moving toward our next attempt at dispensing with the traditional system. Our guiding principle is the hope that this time we will succeed notwithstanding numerous sceptics in various circles who hold that every such attempt must eventually run up against insurmountable obstacles in our situation and must finally end with a return to traditional methods.

Perhaps a science of economics which does not provide an unequivocal guidepost for progressive systems transformations is partly at fault. On the other hand, as many times as decisionmaking centers in Poland have seriously begun to tackle the problems of economic reforms, Polish economics and Polish social thought have furnished plans, ideas, and original, valuable analyses, all of which were not without certain defects.

A basic factor in the explanation of our failures is the fact that the system of operation of the economy is an extremely complex phenomenon and this is why its successful transformation demands a so-called comprehensive approach. This is extremely difficult because of the necessity of operating across an exceedingly broad range, not only in an economic sense, but also socially, politically and educationally, while taking into consideration a very large number of diverse connections, counterconnections and the like.

What is also very important is the circumstance that upon closer analysis it becomes evident that even when these connections occur in some form, as when they assume a technical-economic shape, for example in the sphere of a financial system, a price system or incentive solutions, what in fact is underlying is the sociopolitical content. To put it another way, there is no basic solution in a systems field which does not violate someone else's group interests, or which does not affect the sociopolitical structure, the methods of exercising authority and the role played by various groups and circles. And in this way a multitude of passions is created, each systems approach immediately provokes defensive moves on the part of the threatened groups, which are sometimes very influential. When such a state exists in society that progressive tendencies and forces manage to break down these obstacles, which are, after all, very human and completely natural, then the opportunity will arise to effect a really fundamental change in the economic system.

[Question] We would like to think that we presently have such a state at hand...

[Answer] On each previous occasion we observed an otherwise understandable tendency on the part of decisionmaking representatives to limit themselves to small steps, in order not to jump into the unknown perhaps, and as much as possible to activate

other elements in the socioeconomic policy which could produce substitute effects in place of bolder tasks on the systems front. It became evident that this was an unsuccessful trend. Without bold enough systems changes, without mechanisms guaranteeing the efficient operation of the economy, other measures in economic policy, such as negotiating loans or submitting to growing inflation for the purpose of compelling dynamism are short term, deceptive solutions.

[Question] Very encouraging experiences in our camp are afforded by Hungary...

[Answer] Yes, I agree completely. It is difficult to overestimate the significance of the Hungarian reform. It is really the only example within the CEMA bloc of a successful, bold departure from a traditional system, the replacement of a directive-distributive model by a system in which elements of self-regulation, horizontal ties in the operation of the economy and releasing rank and file initiatives have been introduced and built in much more forcefully than in any other country. This does not mean that I am coming out in favor of imitating Hungarian solutions. I am of the opinion that under our conditions, particularly at present, this would not be good advice.

Certain problems encountered in the Hungarian experience would also have to be avoided. I will mention only two of these. The first: the choice of a managerial, relatively self-governing orientation. In principle the Hungarian reform began with a managerial orientation, but recently certain modifications have occurred in this regard. From the beginning, however, key positions and functions were entrusted to the managerial staff and the role of personnel in decisionmaking processes was not exploited.

In Poland the very situation that we have today predetermined in favor of the second, self-government orientation, in my opinion. Recent agreements and proposals carry far-reaching consequences for all forms of social participation in the operation of the economic system--not only the participation of trade unions, but also of workers' self-governments, national councils, the Sejm and other organs.

A second difference between the Hungarian experience and our experiments would relate to solutions in the field of organizational structures. The Hungarians have highly concentrated, highly monopolized organizational structures. These exist both in their industry and in other economic branches. Even they are not particularly enchanted with this anymore, and we should not remain insensitive to excessive concentration in our systems solutions either. It has been known for a long time, and Lenin wrote in his famous work on imperialism, that every monopoly is at its base the creation of a situation in which nonproductive income is collected. Whoever remains in a monopolistic situation can afford to be insensitive to the needs of management efficiency.

[Question] Is this to say that we would rather draw upon the assumptions of our own model developed during the years 1957-1959?

[Answer] Yes, I hold that the general directions of progressive systems solutions in Poland today are, generally, the same solutions as Polish progressive political and social thought and mass movements outlined during the second half of the 1950's. Our research, of course, has progressed, but the continuity of progressive socio-economic thought is clear.

[Question] What is the significance of recent governmental decisions concerning, among other things, wages and prices, as well as the restructuring of a portion of our production to serve the needs of the market?

[Answer] Naturally price increases complicate the problem of restoring market equilibrium and in this way hamper the systems movement. On the other hand, an inefficient system is a factor which increases the lack of equilibrium.

The immediate attainment of the greatest effects regarding supply is indispensable for the improvement of equilibrium both in the presence of the rapid growth of nominal income and of price stabilizing actions. Consequently, out of social necessity the economic policy is undertaking efforts both externally, to procure additional supplies of the market goods and raw materials necessary for market production, and internally, where it appears that the primary emphasis will be directed toward so-called conversion, or transforming production, when possible, from investment production to production for the market and for export. Particular emphasis will surely be placed on those products and groups of products which are universally felt to belong to the basic components of the living standard. There are rational actions, but...

[Question] With regard to long-term policy only systems solutions can really be successful?

[Answer] Yes, because enormous efficiency reserves are hidden within systems solutions. They are inherent in the possibilities of the full utilization of our production apparatus, the size and quality of which have increased in recent years. They are inherent in the improved utilization of the talents of work crews and cadres, which are more educated and more intelligent than ever before; in the effective use of reserves embedded in our scientific research facilities, which are not productive enough today, but thanks to their intensive former expansion, nonetheless represent very valuable capital for the future.

Positive reserves are also inherent in the fact of the broad internationalization of our economy. While this creates various problems, it also opens up excellent possibilities for deriving the benefits of worldwide production.

With regard to the question of so-called negative reserves, they issue above all from the enormous amount of waste, which grows apace at every turn--the waste of materials, the waste of direct labor, of initiatives and of human ideas. Opportunities have been lost and continue to be lost and the economy is burdened, the reaction to new possibilities and to the needs of people is slow, formal institutions are punctilious with regard to the share of working people in steering the economy. Moreover, there is disintegration within the moral-social sphere.

[Question] But is there not evidence that the situation with regard to the above is of late not as deplorable as we have come to believe?

[Answer] Of course, but the element of optimistic improvement primarily affects only the working class, and of these only large industries.

[Question] What about the issue of the scope of the anticipated reform?

[Answer] In my opinion, it should only be as broad as we can afford under present difficult conditions. For this reason I believe that the reform should be gradually accomplished, in stages. I do not think that in our situation we can be oriented toward a solution in the form of a one-time operation, as in Hungary. Overcoming all of the pressures and imbalances in our economy must be a process...In the scenario of systems changes, roughly speaking, we should set the following course: the execution of a systems movement coordinated with a series of regulatory tasks in socioeconomic policy; as a results of these measures a certain improvement in the market situation follows and puts us in a position to execute the next systems step, which, together with the accompanying actions, produces further positive results for economic equilibrium. And so, by executing these moves as if in "shifts" in the systems field and in other fields, we will be able to complete a progressive restructuring over a period of time.

[Question] And what should the concrete points of departure be? Can they be decisions handed down by premier Pinkowski on such matters as the question of the growth of autonomy of enterprises?

[Answer] In my opinion the principal points of departure are three. First, despite appearances there is the strengthening and social rationalization of central management. This does not mean an increase in directives addressed to economic units. The second point relates to the broader independence of enterprises. In my opinion, we will have to exploit the enterprise as the basic link of the system, the elementary organizational unit of rational management. As its autonomy is broadened, it should be made the primary agent of efficiency. We are becoming more and more acutely aware that the lack of rationality and initiative at the level of this basic unit cannot be replaced with the help of any sort of action from the top.

The third matter is the entire broad social dimension of the problem. To put it another way, the expansion of the share of society, of working people in various sectors in undertaking and implementing decisions in the whole economic process. These are perhaps are three mainstays on which the concept of a new system of economic operation must be based.

[Question] Are the problems of price regulation, of the creation of the appropriate price mechanism, a separate complex of issues?

[Answer] It is perhaps not a separate group, since these problems are intimately involved with the three main subject areas of reform of which I spoke above. The principal changes in the price area would have to be a sine qua non for the introduction of new systems solution in those areas. In the system which--I would like to believe--we will consistently develop, prices should play the role of the

basic parameter controlling the more and more autonomous decisions of enterprises, as well as a factor rationalizing central decisions.

The views that it is possible, by employing models of comprehensive planning, to arrive at the optimal solutions, virtually disregarding prices or using stipulated prices, have not withstood the test of time. The present system of prices with its numerous disproportions continues to be very bad; it does not provide true cost-effectiveness parameters, and consequently is lacking in the basic data for rational economic decisionmaking. It would enormously complicate the expansion of the powers of enterprises to make such decisions.

Actions on the price front cannot but be numerous, difficult to undertake, and very comprehensive all at once, since there are many areas of pricing--retailing, materials supply, foreign trade, procurement and various other prices as well. All of these areas are very specific, but at the same time they are linked through the principle of communicating vessels. Probably one of the most important issues should be restoring the health of the prices of supply for the means of production, which are widely separated from objective conditions today. Fortunately preparations are already underway for actions to rationalize this sphere of price ratios.

[Question] And what of the whole picture of preparations for systems changes?

[Answer] In the near future, groups of experts, decisionmaking teams and staff teams will be called together for the purpose of carrying out conceptual work. Among these people will be politicians, persons in the economics field and scholars. The approach of the authorities to these preparatory activities is ambitious and broad; the overall effort is being directed, as you know, by the chairman of the Council of Ministers. The first "packet" of changes is forecast for 1981.

The announcement that a plenary meeting of the PZPR Central Committee was devoted to the subject of systems changes says a great deal.

Work continues on the plans for a series of laws, which are to be voted on shortly by the Sejm. They will be laws concerning trade unions, workers self-government, and enterprises, and will perhaps include a law on planning. These legal documents, one way or another, have surely already become the expression of a broader concept of the systems changes about which we have spoken.

[Question] The role of the Sejm is visible here, is it not...

[Answer] In speaking of the social rationalization of central management, as one of the mainstays of the whole philosophy of reform, I had in mind the role element executing the selection of the major social tasks and proportions, and then effectively enforcing the execution of its decisions, the social rationalization of central management is impossible to achieve in our system.

[Question] Just as social rationalization at a lower level necessitates the setting in motion of a real self-government...

[Answer] Of course, they are symmetrical. What is needed, however, are conditions of intensive efforts for activating former and new mechanisms of operation of the self-government factor, the social factor, the partnership factor with reference to managers, of central strategists and successive economic decisions. Only then will Polish reform be able to become what it should be...

LONG-RANGE FERTILIZER PRODUCTION, UTILIZATION OUTLINED

Warsaw ZYCIE GOSPODARCZE in Polish No 43, 26 Oct 80 pp 8, 9

[Article by Lech Froelich: "Fertilize and Store"]

[Text] In the opinion of farmers, as confirmed by scientific research, mineral (chemical) fertilizers cause harvesting yields to increase by as much as 60 percent. Fertilization is a necessary but insufficient factor. We have written repeatedly on this subject, as we shall revert to it. In this article we shall chiefly attampt to answer the question of what is the state of the supply of chemical means of production to agriculture.

Fertilizers

The revised 1980 plan provides for a fertilizer output consisting of 1,28 million tons of nitrogenous fertilizers (in terms of the pure ingredient N_2), 845,000 tons of phosphoric fertilizers (in terms of P_2O_5). In the first half of the year the chemical industry produced 641,000 tons of nitrogenous fertilizers, or a little more than 50 percent. It thus should produce 320,000 tons each during the remaining third and fourth quarters in order to meet the planned targets. Despite strikes and emergency stoppages in certain factories--in Wloclawek a production section has been shut down for longterm repairs--in the third quarter our output will fall about 318,000 tons short of the goal, but this shortage can be offset if an adequate supply of raw materials is assured. This concerns chiefly gas, and coal too. If the chemical industry is provided with gas, and if fertilizer production is indeed to be given priority, the industry can fulfill the plan-set targets for nitrogenous fertilizer output.

As regards phosphoric fertilizers, the plan for this year specifies 845,000 tons in terms of P_2O_5. In the first half of the year 449,000 tons, or more than one-half, has been produced. Some 200,000 tons are yet to be produced during each of the third and fourth quarters. The fulfillment of these seemingly easier tasks may, however, be difficult. The plants in Police and Gdansk, though located in the neighborhood of seaports, underwent stoppages owing to strikes, while the plants in Lubon, Ubocze, and Bonarka had production shortfalls owing to lack of phosphoric raw materials, which stayed on board ships. Thus the problem is to deliver these raw materials as soon as possible to those plants and to assure their most efficient and smooth operation until the end of the year.

Chemical industry men comment that this does not, of course, mean that this output and these supplies satisfy completely the demand of agriculture. Farmers always want more. But chemical industry as a producer is bound by the plan. But in their capacity as citizens, chemical industry men are concerned about the manner in which agriculture utilizes chemicals--fertilizers, crop protectants, feed supplements, premixes, vitamins, and antibiotics.

It is obvious besides that chemical industry has other vital tasks to accomplish in addition to helping agriculture. Hence, the necessary developmental proportions in the structure of that industry must be maintained. In the last 15 years (1963-1978) the supply of chemical fertilizers (NPK) [nitrogen, phosphorus, and potassium] to agriculture has grown from 56.4 to 190.3 kg per hectare, that is, by a factor of 3.5 times. This has required considerable investment outlays. It is estimated that in view of the considerable capital-intensiveness of investments in the nitrogenous and phosphoric fertilizers industry every additional kilogram of these fertilizers per hectare on the nationwide scale requires 1.5 billion zlotys in investments in the fertilizer industry! How were these fertilizers utilized? In the last 15 years the average grain harvest increased by a factor of 1.6 times; the potato harvest, by a factor of 1.3; and the sugar beet harvest, by a factor of only 1.1.

As for potassic fertilizers, we import them. Until 1978 it was thought that we had a surplus of potash, and dumps of potash salt had lain on depots of state farms and PR. Scientists have shown that the proper proportions between the supply and application of nitrogen (N_2), phosphorus (P_2O_5) and potassium (K_2O) should be 1:0.8:1.2. Agriculture in 1980 will receive enough fertilizers to reach the ceiling of 192 NPK per hectare of arable land. This is much less than envisaged in the 1973 Program for the Chemicalization of the National Economy, and less than the 1976-1980 Five-Year Plan. Even so, however, during the 1973-1980 period application of chemical fertilizers will have increased by 26.5 kg per hectare.

An Exchange of Views

Between chemical industry and agriculture a fairly lively exchange of opinions occurs on the manner in which fertilizer production should develop in the next few years and on the amount of fertilizers that should be given to agriculture in order to attain the anticipated harvests. Agriculture (in its postulates of August 1980) expects the fertilizer industry to develop on a scale assurinf the supply of 1.8 million tons of N_2, 1.2 million tons of P_2O_5 and 170,000 tons of K_2O to agriculture by the year 1985; altogether this amounts to 4.7 million tons of fertilizers and it would serve to improve the degree of fertilization by 58 kg per hectare compared with the current year, that is, to raise the level of fertilization to 250 kg NPK per hectare. -

The Ministry of Chemical Industry is very optimistic about the possibility of raising the level offertilization fo 230 kg per hectare in 1985, that is, by 38 kg more per hectare than at present. The supplies would then amount to 1.7 million tons of N_2, 1.1 million tons of P_2O_5 and 1.55 million tons of K_2O, or a total of 4.35 million tons. Assuming that every additional kilogram of fertilizers per hectare on the national scale costs 1.5 billion zlotys in investment outlays,

the implementation of such a program would cost 57 billion zlotys! At any rate, more than 50 billion zlotys. This year the Ministry of Chemical Industry expects to spend 7.6 billion zlotys(including 2.2 billion zlotys on the [fertilizer plant] in Police) on all investments relating to the food economy.

Farmers base their claims on the following arguments: the lower fertilizer output and smaller application doses proposed by the chemical industry will result in an application shortfall of 1.46 million tons of fertilizers during the 1981-1985 period. Since it is recognized that each additional kilogram of fertilizers applied per hectare results in a average increase of 6 kg in grain harvest per hectare, the overall grain harvest during that 5-year period will be 8.7 million tons lower, or on the average 1.7 million tons lower each year!

This reasoning cannot, however, be accepted without law of diminishing returns reservations. A certain degression rather than direct proportion exists between the increase in amount of chemical fertilizers applied and the increase in yields. Thus, it is believed that for the first 100 kg NPK applied per hectare every 1 kg applied results in an increase of 5.8 kg in grain yields, but within the 100-200 kg per hectare range every kg applied results in an increase of only 3.5 kg in grain yields, while within the intensive 200-300 kg per hectare range every kg applied results in an increase of only 2.0 kg in grain yields, so that achieving higher harvests in this way becomes increasingly costly. Moreover, the calculations of "decrease" and "increase" in yields should be limited to the approximately 14.6 million bectares of tilled land alone, rather than covering the whole of arable lands--about 19 million hectares.

If agriculture in 1985 were to receive 38 kg NPK per hectare more than it does at present, it should harvest 228 kg of grain more per hectare, or more than 4.3 million tons on the national scale.

Crop Protectants

Will chemical industry supply them in the quantities needed?

Since the production of crop protectants is to some extent based on imported semi-finished products or concentrates of the active substance, their supply is lower than the demand of agriculture. The extent of satisfaction of that demand as regards herbicides and fungicides is estimated at 40-50 percent. Although there are quite a few original new technological solutions and even design documents on the shelves of institutes, the program for developing the pesticide base has been imprlemented only minimally. It had been expected that 6 billion zlotys would be spent for that purpose during 1976-1980, but only 600 million has been spent.

Moreover, a "humorous" dialogue between chemical industry and agriculture recurs every year. Farmers need crop protectants for the brief spring-summer vegetation season and it is always then that they clamor about the scarcity of these chemicals. On the other hand, it must be borne in mind that most of the chemical industry's production facilities operate continuously and without any large margin of reserve. Thus during individual months and quarters of the year the scale of output and supply does not vary much. Farmers demand multiplied deliveries during the several "active" months. The crop protectant factories,

which operate more or less smoothly throughout the year, can only provide about one-twelfth of annual deliveries each month. Hence this relationship between "smooth" production and "activity" of utilization of crop protectants should be taken into account in the system for receiving orders and purchases.

This year, during the period of its "action" [drive]--because the drive for combatting pests and weeds begins and ends at definite periods--agriculture received 99 percent of the plan-envisaged potato beetle pesticides, 112 percent of grain herbicides, 105 percent of sugar beet herbicides, 95 percent of corn herbicides, and only 55 percent rape pesticides. It should be noted, however, that this year climate anomalies and floods destroyed large areas planted with rape which had to be plowed back, so that the demand for rape crop protectants has diminished. As for the supply of crop protectants for orchards, it reached 105 percent.

For a long time now opinions have been differing about whether priority should be given to fertilization, that is, to yield-increasing operations, or to a broader application of preparations reducing losses and protecting the harvests on the field and in granaries and silos.

Last year the aggregate harvest of the four cereals amounted to 15.3 million tons, reaching 27.7 billion zlotys in value. When applied in accordance with the rules of agrotechnology, crop protectants reduce harvest losses by 10-15 percent, which means that it is possible to gain at least 1.5 billion tons more of grain having a value of nearly 3 billion zlotys. The cost of producing crop protectants (or importing them) or the eventual investment outlays on the construction or expansion of the necessary facilities is much lower than in the artificial fertilizers industry. This also applies to the so-called preservatives--preparations serving to protect what has already been grown. In this country storage losses reach 15-20 percent. These figures should serve as a basis for answering whether investments should be concentrated in the capital-intensive and energy-intensive production of fertilizers or whether the needed increases in yields should be achieved in another way. By eliminating these storage losses we could gain at least 3 million tons of grain annually. This does not, of course, mean thta the chemical industry's fertilizer program should be abandoned. It is simply that both possibilities should be borne in mind.

REPORT ON THE FULFILLMENT OF 9-MONTH ECONOMIC PLAN

Sofia RABOTNICHESKO DELO in Bulgariar 25 Oct 80 pp 1, 2

[Information by the Committee on the Unified System of Social Information at the Council of Ministers Regarding Fulfillment of the Unified Plan for Socioeconomic Development of the People's Republic of Bulgaria During the 9-Month Period of 1980]

[Text] During the past 9 months the workers embarked on a nationwide socialist competition and met the 36th anniversary of the 9 September Revolution with new achievements by fulfilling the 1980 as well as the Seventh Five-Year Plan. The July Plenum of the BCP Central Committee (1980) gave the impetus for mobilizing the creative forces and energy of the people to work further for a stable and intensive development of the national economy and for a worthy welcoming of the 12th Party Congress.

As a result of applying the economic approach and the new economic mechanism, the plan for net production, social productivity, profits, and cost price has been fulfilled.

The plan for scientific research and applied engineering, which contributed to better utilization of the scientific-technical achievements, has also been fulfilled.

Building and improving the material-technical basis of the national economy continued. For the 9-month period 3.8 billion leva capital investments were adopted, of which 1.8 billion leva were used up for renovation, modernization and expansion, i.e. 56.8 percent of the anticipated sum by the yearly plan.

A great number of labor collectives reported fulfillment of the Seventh Five-Year Plan as a result of the nationwide socialist competition, of the introduction of a new type brigade labor organization all along the line, and of wide application of exemplary achievements.

I. Industry

The economy complexes, ministries and other departments, the economic enterprises and their branches in industry, fulfilled the 9-month plan for monetary revenues by 100.7 percent regarding realization of commodity production and 101.0 percent regarding produced commodities.

All okrugs fulfilled the plan for produced commodities. The okrugs of Blagoevgrad, Varna, Mikhailovgrad, Pernik and Smolyan did not reach the required results of monetary revenues from realized commodity production.

Some economic organizations did not obtain the expected monetary revenues from realization of commodity production either, as for example: Bulgarplod [Bulgarian Fruit], DSO [State Economic Trust], Dimitrovgrad Chemical Combine, SK [Economic Combine] for household electric appliances, Yambol Dimiter Dimov chemical combine, and others.

Per basic economic ministries and departments the plan fulfillment for the 9-month period stands as follows:

	Percent of the plan fulfillment for 9-month period	
	Produced commodities	Monetary revenues from realized commodity output
Ministry of Energy	100.2	102.3
Ministry of Chemical Industry	100.3	100.9
Ministry of Machine Building	100.0	102.1
Ministry of Electronics and Electrical Engineering	101.2	101.6
Ministry of Light Industry	102.9	102.5
Ministry of Metallurgy and Mineral Resources	102.9	100.5
Ministry of Transportation	99.8	97.1
Ministry of Internal Trade and Public Services	103.8	102.5

Overfulfilled was the 9-month plan for production of electric power, rolled ferrous metals, electric hoists, electric telfers, power transformers, soda ash, nitrogen fertilizers, and others.

Some economic organizations and departments did not fulfill their plan for production of cast iron, lathes, electric motors, shoes and some other commodities, and, thus, did not supply the consumers with the contractual consumer goods.

Use of machines and equipment expanded in many fields of industry. In some workshops and plants the new technology and techniques have not been adopted and the expected technical-economic indicators of installed machines and equipment in industry have not been reached.

A greater growth of net production in industry has been reached by smaller material expenditures and by improved rationalization of production and better utilization of the existing resources during the 9-month period.

The production of some basic goods is characterized as follows:

	Unit	Produced Output	Percent of Plan Fulfillment
Electric power	million kWh	25,200	100.2
Cast iron for processing	tons	1,162,213	99.0
Rolled ferrous metals	tons	2,302,301	100.2
Lathes	units	6,798	99.7
Electric hoists	units	33,536	103.7
Electric telfers	units	86,635	101.6
Electric motors	units	920,314	99.9
Internal combustion engines	units	10,550	100.0
Power transformers	units	5,658	103.9
Soda ash	tons	1,109,516	102.4
Nitrogen fertilizers (including carbamide)	tons	549,777	100.9
Cotton fabrics	thousand meters	252,919	103.4
Shoes	thousand pairs	12,585	98.9
Meat	tons	332,871	101.1
Butter	tons	16,505	100.3
Sterilized canned vegetables	tons	169,507	85.1

II. Agriculture and Livestock Husbandry

In the past 9 months of the year the material-technical basis of agriculture and livestock husbandry continued to expand. For this purpose 576 million capital investments were used up. The plan for supply of chemical fertilizers is progressing successfully. Agricultural work was done under unusual meteorological conditions, i.e. high precipitation and low temperatures in spring and significant hot spells and drought in June and July. Not all areas designated by the plan were seeded. Normal vegetation of some crops was delayed and interrupted. Some other crops, however, are expected to give good yields.

Good conditions were created for balancing off part of the losses caused by the unfavorable meteorological conditions.

Average yield per cow increased by 26 liters compared to 1979, or 1.1 percent. Average egg-laying capacity decreased, although egg production increased due to a greater number of layers.

The number of animals and fowl at the economic enterprises and departments is as follows:

	1 October 1980	1 October 1980 in percent compared to 1 October 1979
Cattle	1,447,328	99.9
Of which--cows	493,971	100.2
Pigs	2,989,221	99.5
Sheep	6,674,313	96.8
Fowl	27,744,249	103.1

In the same 9-month period a smaller number of cattle and fowl designated for meat and milk production was bought out from all categories of farms, while the number of eggs bought out increased.

III. Construction

The construction and assembly organizations fulfilled their 9-month plan by 95.4 percent and their yearly plan--by 69.5 percent.

The 9-month plan for putting into operation the fixed assets was also fulfilled.

In the 9-month period many important projects were still faced with shortcomings in their organization of the work, and could not obtain sufficient number of skilled labor and adequate construction technology. Some construction projects were not put into operation on schedule, as for example: the Radomir plant for heavy machinery, the first technological line of Temelkovo V. Kolarov DTsZ [state cement plant], the expansion of Lenin SMK [construction and installation combine], and the renovation and modernization of Kremikovsti SMK.

The plan for completing and putting into operation housing projects, day care centers and kindergartens was not fulfilled.

IV. Environmental Protection

Over 142 million leva were used in the 9-month period for different undertakings and for construction of projects with the purpose of meeting the environmental protection standards. New electric filter systems were put into operation in the agglomerate production at the Sofia Kremikhovtsi SMK, and in the V. Pik DTsZ in the village of Beli Izvor, in the purifying station of the Gabrovo D. Blagoev plant, in the reproduction bases in the villages of Byala Rada and Kalchevo, in the slurry pond in Rosen, and others.

The program for application of nonpolluting technologies in production and for water recycling systems continued to expand.

V. Transportation and Communications

The 9-month plan for revenues from transportation, loading and unloading as well as shipping by the general transportation system was fulfilled 101.1 percent.

The transport economic organizations fulfilled their freight plan 93.5 percent.

The plan for passengers transportation was fulfilled 102.6 percent.

The plan for revenue from postal, telegraph, telephone, radio and television services was fulfilled 101.4 percent. The postal system was expanded by 20 PTT [posts, telegraphs and telephones] stations. Some 88,521 new telephones were installed, 72,279 of them in private homes. A total of 193 new telex connections were put into operation.

VI. Foreign Trade

In the 9-month period foreign trade increased by 13.6 percent, compared to the same period of last year.

Structural changes in the export system were introduced with very promising results. The share of high-quality processed goods increased considerably. Machines and equipment represent the largest share of the total export, i.e. 44.9 percent.

In the 9-month period the People's Republic of Bulgaria was visited by 4.7 million foreigners from 149 different countries. The number of visitors increased 10.6 percent over the same period of last year.

VII. Standard of Living

In the 9-month period commodity production designated for the domestic markets was expanded, as well as the everyday regular services of the people.

Trade organizations were granted 2.6 percent more goods of domestic production than the contractual allocations. More food (1.3 percent) and nonfood (3.9 percent) products were supplied than the contractual quantities.

The retail turnover plan was fulfilled 102.2 percent.

Larger quantities of the following goods were sold to the people: poultry, sugar products, milk, eggs, wool fabrics, silk fabrics, ready-made clothes, knit outerwear, shoes, furniture, radio sets, sewing machines, passenger automobiles. Due to lack of commodity funds, some goods in some districts were missing from the market.

The plan for services for the same period was fulfilled 102.0 percent. Servicing does not meet the increased needs of the population in spite of the good results in the upkeep and renovation work of the radio-television system and in furniture and carpentry services, as well as in the shoe, leather, haberdashery, textile, knit and clothing businesses.

The plan for upkeep and repair of appliances, motor transportation means, dry cleaning, and construction-repair services was not fulfilled.

About 35 thousand dwellings were built during the 9-month period of the year.

Considerable sums were spent for development of education, cultural life and health services. The school and kindergarten system was expanded. New premises were built as follows: kindergartens for 3,768 children, daycare centers for 480, and schools of general education for 4,661.

In this same period of the year the average monthly salary reached 186 leva in industry and 203 leva in construction.

The achieved results in the past 9-month period, the political and labor upswing involving all the people are a promising guarantee for a successful conclusion of 1980 and the seventh 5-year period, for a worthy welcoming of 1981, the year of the 12th BCP Congress.

MINISTER EXPLAINS SET OF MEASURES IN TV INTERVIEW

Prague TV in Czech 1740 GMT 23 Oct 80

[Summary] Ladislav Supka, the CSSR minister for investment and technological development, gave a TV interview to a number of reporters from the major dailies who questioned him on the implementing procedures for the next five-year plan which is to be based on the Set of Measures starting on 1 January 1981. In the course of the interview, the minister noted some shortcomings such as non-implementation of the results of the Research Institutes' findings and inventions in practice, often because of the lack of investment planning. For example, very significant improvements were designed for the UZ-2 and UZ-3 tractors in 1977; however, the production planned for the 1978-79 period could not be started because the required Kcs 5 billion in investment was not available for the production line changeover to the new model UZ-1 tractor, causing large indirect losses to the CSSR economy, since the tractors would have been of exportable quality and could have earned foreign currency.

Another problem mentioned was the aging construction labor. The minister allowed that a foreman needs broad experience, yet the young people were not being afforded opportunity to train for and advance into such positions because of their "lack of skills" and there is presently no personnel available to "step up into their shoes."

On the question of licensing policy, the minister stressed the advantages of exchanges and quoted 91 purchases of licenses from, and 85 sales to, the Warsaw Pact countries while there were 163 purchases from, and 94 sales to, the Western countries during the 1976-79 period; however, foreign currency earnings are a problem. "Each case," the minister said, "must be evaluated in terms of required expenditures not only for the foreign licenses but also for certain materials, parts, and specialized machinery not available domestically, so that even if the final product is exported, these costs must be balanced in terms of expenditures vs. earnings of foreign currency."

On the question of capital investments, the minister noted the shortages of labor to man the new factories and stressed instead the improvement of the existing plant and equipment by installation of automated mechanisms and robots on the production lines to make them more productive; although, as Mr Supka qualified, this may require some switching of personnel and retraining them to make these new mechanisms.

Another problem, according to the minister, is an excessive number of different engineering products being made in the CSSR, nearly twice as many as in the United States. This is complicated by the fact that decisions will have to be made as to which lines of products should be dropped, a measure which will also cause some restructuring of the industry. In this context, the minister noted that most of these industries are concentrated in just a few population centers (or engineering production concentrations, as Mr Supka referred to them) which account for a high proportion of the CSSR manufactured products and any changes could require populations shifts.

Mr Supka also touched on the difficulties in the field of electronics where, as he pointed out, CSSR is quite competent and is producing competitive quality Large and Very Large Integrated units, except that the quantities are so insignificant that they do not even cover the needs of the country.

Commenting on a question about the housing situation, the minister explained that, even though the next five-year plan calls for a construction of 550,000 housing units as compared with the present five-year plan of 650,000, it is expected that 100,000 fewer units which have outlived their usefulness would be torn down so that the net result would be the same in both five-year plans. In reply to the last question, the minister compared the old concept of "Key Development Projects" in the fuels and energy industry to the new concept of "State Goal-Oriented Programs" which, under the new criteria, will place much greater emphasis on energy conservation. He also said that there will be about 30 percent fewer of the new programs than of the "Key Projects" and they will be more realistic. He also indicated that the CSSR industry was 30 percent more energy intensive than that in the West and that improvement there was imperative to survival. Standards in this field must be brought up to the Western levels within the next five-year plan.

CSO: 2400

ORDER ON GENERAL TRAFFIC PLANNING PUBLISHED

East Berlin GESETZBLATT DER DEUTSCHEN DEMOKRATISCHEN REPUBLIK in German Part I No 27, 1 Oct 80 pp 270-272

[Official text of "Order on General Traffic Planning, dated 28 July 1980," signed by State Secretary Dr Schmidt for the Minister for Transportation, East Berlin]

[Text] In agreement with the heads of the competent central stage organs the following has been ordered:

Article 1

Field of Validity

(1) This order regulates the tasks, rights, duties and responsibilities of the state and economic management organs as well as of enterprises, combines, cooperatives and institutions in the context of general traffic planning.

(2) This order applies to the general traffic plans of

--the GDR bezirks,

--the GDR capital, Berlin, in the framework of the general plan,

--the bezirk towns and those towns and areas designated by the bezirk councils in agreement with the Ministry for Transportation.

Article 2

Principles of General Traffic Planning

(1) General traffic planning is effectuated on the basis of legal prescriptions, decisions of the Council of Ministers, on determinations of the minister for transportation and proposals of the local councils. The development programs of CEMA are to be given special consideration in this context.

(2) The general traffic plans are instruments of the Ministry for Transportation, of the local representative institutions and of their councils for the comprehensive planning and preparation of general traffic development in each territory in harmony with the overall traffic development of the GDR.

(3) The general traffic plans must comprise a time span of at least 15 years. The measures for the development of traffic installations conceptualized in these plans are to be ordered according to ranking and sequencing, in a manner such as to indicate utilizable subcomponents. Every bezirk general traffic plan is to be harmonized with the general traffic plans of the neighboring bezirks. The general traffic plans of towns are to be prepared on the basis of the development of the transportation system determined in the general traffic plan of the respective bezirk.

(4) In the preparation of the general traffic plans the planned spatial distribution of productive forces is to be taken as the point of departure, taking into account that in the process of general traffic planning an influence is to be exerted on the conceptions for the spatial distribution of productive forces in the interest of effective development possibilities of the traffic system. Beyond this, the mutual and reciprocal relations with the general development and buildup plans and other plans of territorial development are to be taken into account.

(5) The general traffic plans are to be elaborated in complex cooperation with the state and economic management organs, enterprises, combines, cooperatives and institutions. In particular, the collaboration of the organs of territorial planning, construction, of the German People's Police, the regional military commands, the energy supply organizations, environmental protection and water economy, and of the German Post Office is to be secured, as is the inclusion of the competent commissions of the local representative institutions and of the social organizations.

(6) The general traffic plans are to be updated and qualified continuously in dependence on the course of social development. General traffic plans require the agreement of the minister for transportation with respect to the basic lines of traffic policy before they are submitted for decision to the local representative institutions or their councils.

(7) In the preparation of general traffic plans it is to be taken as point of departure that claims on agriculturally utilized land must be excluded to the largest extent possible. The Order of 17 December 1964 for the Protection of Agricultural and Forestry Lands and for the Securing of Socialist Land Utilization--the Land Utilization Order (GESETZBLATT Part II, 1965, No 32, p 233) is to be observed in this context.

Article 3

Content of General Traffic Planning

(1) Taking their point of departure from the societal and scientific-technical development, the general traffic plans have to cover the following foci:

(a) traffic policy target setting for the territory at issue;

(b) development of passenger and freight transportation requirements;

(c) maintenance and expansion of transportation infrastructure;

(d) development of passenger and freight traffic systems, including short-distance [commutation] traffic systems, individual traffic and intraplant traffic;

(e) development of the division of labor in passenger and freight traffic;

(f) development of traffic organisation;

(g) listing of areas to be kept unencumbered for the construction and expansion of transportation infrastructure and other traffic installations;

(h) evaluation of the traffic solutions conceptualized in the general traffic plan.

(2) In the preparation of general traffic plans, the requirements of socialist intensification and rationalization, of socialist economic integration, of national defense, of the development of mining, energy and water economy, of environmental culture and protection, of the German Post Office and of traffic safety are to be given specific attention. One of the requirements of traffic safety is the special protection of children on the roads from their homes to children's institutions and schools.

Article 4

Tasks of the Local Councils

(1) The local councils prepare the general traffic plans for their territories and implement them. In this context, the orientation in the general traffic planning of towns is to be toward an especially close collaboration with the development of building planning, on the basis of uniform assumptions and time scheduling. The local councils submit the general traffic plans to the competent local representative institutions for decision.

(2) The member of the local council responsible for transportation matters guides the preparation of the general traffic plans and their translation into the framework of 5-year and annual planning and exercises control over the execution of the measures decided upon.

(3) The member of the bezirk council responsible for transportation matters has to submit the general traffic plans to the minister for transportation for his approval of the basic directions of traffic policy in good time prior to the intended passage of a decision by the bezirk diet or the assembly of town deputies.

(4) The local councils insure the maintenance of open areas to the degree required for the realization of the general traffic plans.

Article 5

Tasks of the Ministry for Transportation

(1) The minister for transportation lays down principles for the formation of general traffic planning. He guarantees that the specialized organs of the bezirk councils responsible for traffic are guided and controlled in the preparation of general traffic plans.

(2) The Ministry for Transportation guides the institutions for the traffic planning of bezirks and towns in general traffic planning regulates the principles for the determination of their missions and their working procedures and organizes the exchange of experiences for this purpose.

(3) The Ministry for Transportation guarantees that the management organs, combines, enterprises, offices and institutions of the centrally managed transportation system collaborate in the elaboration, updating and specification of the general traffic plans.

(4) The minister for transportation makes arrangements for the evaluation of the basic principles of traffic policy of the general traffic plans which have to be submitted to him for approval and transmits these evaluations to the respective bezirk councils together with recommendations and indications within 6 months.

Article 6

Binding Force

(1) Taking into account their ranking and sequencing in the framework of state plan indicators and other binding targets, the determinations and targets of the general traffic plans are a basis for the preparation of the 5-year plans and the annual economic plans.

(2) A binding obligation for all state and economic management organs, enterprises, combines, cooperatives and institutions in the given territory to implement determinations of the general traffic plans which require material and financial expenditures is given by the passage of the resolutions on the national economic plans.

Article 7

Concluding Regulations

(1) The present order assumes validity with its publication.

(2) At the same time the order of 10 January 1976 on General Traffic Planning (GESETZBLATT Part I, No 3, p 41) loses validity.

MANAGEMENT TO BE RESPONSIBLE FOR IMPROVED PATENT RIGHTS SYSTEM

East Berlin EINHEIT in German Vol 35 No 10, signed to press 11 Sep 80 pp 1030-1034

[Article by Hans Kuegler, engineer, director, Patent Rights Office, VEB Carl Zeiss Combine, Jena; and Prof Dr Klaus Muetze, engineer, director of combine's Research Center: "Top Performance Requires Purposeful Patent Rights Work—Experiences in the VEB Carl Zeiss Combine, Jena"]

[Text] Inventions crucially control the degree of novelty and the use value of the products, represent the status of development in science and technology, and affect the developmental level of industrial production. An essential management task amounts to promoting invention efforts and, with it, protecting their results in accordance with legal principles. The authors are reporting on how, through various measures, invention activities are purposefully directed and stimulated. Experiences with patent rights work are presented, and necessary conclusions are drawn from them.

Attaining the requisite higher level of scientific-technical work on behalf of significantly improving our economic efficiency, reaching and economically utilizing top performances at a much broader scope, make growing demands on the creative work of the working people, mainly the researchers, scientists and engineers. Here it is becoming increasingly important to achieve an emphatic impetus for producing and using inventions and providing legal protection for them, whereby to perform a greater contribution to economic efficiency and quality improvements.

Inventions decisively and measurably reflect the developmental status of science and technology. They crucially control the degree of novelty and the use value of the desired products and the scientific-technical level of procedures and technologies, hence, the developmental status of industrial production. It thus is in the interest of our society to make extensive use of these inventions in our own country and make them available, on the basis of state agreements, to our fraternally allied CEMA countries. At the same time it is important to protect them against uncontrolled grasps from capitalist states and corporations.

To protect the interests of our state and of the inventors, our socialist patent right was established, the economic patent, which goes back to the principles formulated by Lenin as long ago as in 1919 in the decree on inventions and discoveries. It grants the socialist state an unrestricted authority to use protected inventions, creates protection form competitors in the capitalist economy, and insures inventors of their adequate recognition. The economic patent encourages creative achievements, places the use of protected inventions under state control, and thus makes possible their systematic utilization. The norms by which the patent rights work is to be organized and realized and integrated with the planned reproduction process are set down in legal regulations in which also are included the tasks resulting from the patent rights agreements among the socialist countries.

Clear Requirements

The responsibility of the combines and enterprises for organizing the reproduction process includes the task of managing invention activity and patent rights work and use its results so that it conforms with economic expectations. That calls for concrete tasks with regard to economic use in terms of producing and using patent information and documentation, the planning and management of invention activities, the registration, defense and enforcement of our own patent rights and their contest with foreign ones, the use, secondary use and licensing activity in a national and international framework, and the moral and material recognition of the working people's creative achievements.[1]

The basis for managing invention activity and patent rights work in our VEB Carl Zeiss Combine is the scientific-technical and economic development which--proceeding from international trends and governmental prognostic and longe-range considerations--is being planned for optimizing precision equipment construction in our economy. Our point of departure is the task our combine has to produce top products of precision equipment in optics, 70 percent of which determine or codetermine international standards, most of which are being exported, which are legally without fault and have a high degree of novelty and use value and have stood up through a marketing period of from 3 to 5 years. That calls for scientific-technical and economic requirements for developing new products oriented to high qualities and performance efficiency and to greatly reducing the time frame of R&D, whereby they also challenge the personnel's pleasure of work, dedication and creativity. When tasks are not clear, corrections are needed and poor results are the consequence. In any event, we are losing time then, and that is harmful to us in our international competition.

Clear requirements for the future call for accurately determining our position at present as it can only come from implacable comparisons with international standards. To that end we must ascertain present international standards extensively--not only by looking at the equipment made by the competitors but also, thoroughly, at the literature--and compare the results we seek in our products with them. It is largely thanks to our rigid and purposive management activity and our indefatigable political-ideological work that our combine now has practically accepted as an axiom not only to compare, for preparing correct objectives, the new product to be developed with what is now the best foreign product and with our own product that is to be superseded by it, but also with

the kind of product which, as determined by trend analyses, might presumably be offered by the competitors at the time that our own product is put on the market. In the outcome of all these comparisons, those requirements are laid down, at the start of our own development, that are, with respect to the use value factors and the costs of the new product, apparent when looked at in terms of when the product comes on the market.

Even when we set down these objectives for a product under development we must place correct and concrete major emphases for invention activity and patent rights work. Being the part of the R&D process that most strongly affects creativity, the strictest attention must be paid to invention activity in the preparation of R&D themes, the derivation of scientific-technical and economic targets, the demands for use value characteristics and the quality and the materials economy of a planned product.

As practice has confirmed, the use value of a product depends, not last, on how those who are working in R&D, especially the managers, are able to make inferences from what they know of descriptions of previous inventions, can process it creatively, and themselves obtain solutions qualifying for patent protection. Thoroughly studying patent literature often proves most valuable when one is looking for new solutions because the description of inventions must indicate how the invention is to function and such a description in many countries is published by the patent office as soon as 1 1/2 years after the patent was registered, at a time, in other words, when the equipment under development has normally not yet led to sales products.

That is why, in managing scientific-technical work, we focus on conducting patent rights analyses while carefully exploiting research results from the patent literature. Such analyses have in our combine increasingly been integrated with the process of target assignments, especially with the derivation of technical requirements, in order to obtain parameters that control international standards and R&D results legally without fault. Patent rights measures were set down in patent rights conceptions which are, in principle, being elaborated in our combine today for the initial defense of any R&D theme.

The starting point, contained in these conceptions, for the task to be solved by invention is the scientific-technical task set down on the basis of information from the literature, especially patent literature, and of what is known about competing products and about the desires of our customers. Quite a number of demands for new solutions arise here where what is known and the facts ascertained are not likely to be adequate. And these precisely are the tasks that are to be solved by invention. They are set down in the duty notebook and already play a role in the initial defense and thereafter all through the further course the theme undergoes. On behalf of continuity for the work process, the solutions one expects also have to be specified in terms of time and accounted for.

In solving scheduled tasks in the R&D areas inventions are being suggested for which the patent rights bureau conducts the innovation tests the law requires. If the inventions appear protectable, it is necessary, for the sake of later sales and exports, to do everything needed for their comprehensive protection

as early as possible. To that end, from the vantage point of our country's economic interest, the proper patent rights applications are prepared jointly between the R&D areas and the inventors. As any protected invention clearly presents a solution exceeding our state of technology and is a source for a novel or improved use value, the GDR can then make extensive use of it as soon as the patent registration was made. To fully utilize all possibilities free from patent restictions in the country by using our patents, we seek their widest possible application not only right after they were registered but also through annually recurring controls. The value estimated from the use of an invention, furthermore, is an essential criterion for whether or not it is worth applying for patent rights abroad.

Among all the measures and conditions that serve stimulating invention achievements is that these achievements are morally and materially recognized. That starts with including invention activity in socialist competition which is given moral and material recognition and is accounted for monthly. It continues in a diversified type of payment for recognition when a patent is registered in the GDR that has been tested for its innovative quality, in publicly handing the documents for tested patents over before the entire collective of the research center or the enterprise, in the payments for confirmed and used economic patents, together with an appreciation letter from the general director of the combine, and in the payment of legally admissible compensations for giving out licenses.

Rigid Management, Planning and Organization

Beginning with the planning process, all possibilities must be used to manage systematically and rigidly the work of invention or the patent rights work needed for the development of new products and new procedures. That is why these processes are being prepared in a target-directed manner in the combine in coordination with long-term and annual management and planning documents. That includes that clear tasks are assigned in the development areas and that the tasks of inventions are planned for processing any R&D theme.

Basic objectives for inventions and for patent rights work are elaborated on the basis of the scientific-technical and economic objectives for the development of the combine or the research center. Through our intensification conception, their lead-time provisions are envisaged for the long-term planning period. The priority within such objectives goes to the assignments for the development of feasibility studies to be prepared with special attention to the major tasking areas in the product and procedure development. In conformity with our intensification conception, more specific objectives are also set down for inventions and patent rights in the more long-range development conceptions of the product groups. Through these conceptions we elaborate and determine for any given products group (or cross-sectional area) the R&D targets and tasks for the next 5 to 10 years and the ways and means, measures and decision proposals for implementing those targets. We always see to it here that analyses carried out on the state of our technology, based on patent rights literature, will faciitate and improve the foundations of the elaboration of the scientific-technical and economic objectives for the various product groups.

While preparing and elaborating annual plans--related to areas and themes--, parameters and qualitative demands are assigned, especially with regard to the fruitfulness of inventions, the level of the inventions, and the patent rights analyses and conceptions. Such assignments notably focus on fundamental inventions with crucial functional parameters and on completing the tasks within assigned schedules.

Patent rights work in the combine is the responsibility of the director of the research center, the director responsible for the R&D of the Central Bureau for Patent Rights. This creates the prerequisites for uniform management combining with the R&D processes, making the function of the combine all-inclusive. The Central Bureau is responsible, in particular, for the planning and coordination of patent rights work in the combine, its effective organization and the development of creative work on the part of inventors and of the originators of industrial models.

The combine's enterprises have their industrial bureaus or patent rights agents. Whereas the industrial bureaus are responsible almost for all the patent rights work, except for activities in other states, the agents exercise exclusively intra-plant functions.

So that skilled decisions can be made on patent rights problems and appropriate measures be purposefully enforced, patent rights collectives are working in the development areas. It is up to them to elaborate appropriate analyses and conceptions, prepare decisions on patent rights applications abroad, test the usability of patent rights and make recommendations for their utilization.

Future Focal Points

If inventions and patent rights work have developed positively in our combine between 1976 and 1980, most of the credit has to go to our continuity in management which led to increasingly more systematic working methods in the whole field and, especially, to a systematic implementation of assignments. Managerial focal points clearly lay on invention activity and on the economic utilization of protected knowledge.

The following table presents a survey of some of the results of our work (data in percentages, always with reference to 1976):

	1977	1978	1979
Invention proposals	100	116	129
Invention proposals per number of employees	95	112	118
Patent registrations GDR	98	148	141
abroad	104	83	199
Patent inventory GDR	111	124	145
abroad	111	115	103
Use	248	315	310
Patent rights analyses and conceptions	245	463	1,041

With all the advances made, we seek further to increase in the future our productivity in patents and to register as patents more of the patent proposals

submitted in the GDR. To that end, we must further improve the level of management in invention activity and patent rights work altogether. To that end it is imperative to combine that still more closely with R&D and to deepen the existing interaction.

Above all, inventions and patent rights work ought to exercise a stronger influence still on the R&D process early in the game. Even when basic and preparatory research is done these problems ought to be given the greatest attention. This involves in particular our cooperation with academies, universities and colleges for systematically elaborating inventions that determine fundamental and total lines of development. Patent rights analyses and conceptions must become still more effective mainly in preparing requirements for R&D themes. They must affect our scientific-technical level and guarantee a no-fault legality as required on behalf of an unlimited market efficacy of new products. Altogether it is necessary to take into account in the management of patent rights work more than we have done in the past that it is to make a greater contribution to improving foreign economy results. A precondition for that is, not last, a more active patent rights activity abroad based on good familiarity with the competition and market situation. On that premise, proper inferences can be drawn with regard to the importance of an invention, the range of its use, the export countries envisaged and the economic benefit resulting for economic activity from maintaining our patent rights. This patent rights activity includes our carefully watching the patent rights activities of our competition. Growing attention also is warranted for permanently organizing an extensive use and secondary use of inventions aiming at a better economic utilization of them.

In placing higher demands on patent rights work in the future, we are convinced that this way the efficiency of our whole reproduction process, from R&D via production to sales on the world market, can be decisively improved and our combine can make a greater contribution to increasing our republic's national revenue.

FOOTNOTE

1. The Patent Rights Decree for R&D, Production and the Foreign Economy (GBL, Part I, No 15, 1974) provides the details on these measures--from the analysis of patent rights literature, the elaboration of patent rights analyses and conceptions, all the way to acquiring and maintaining patent rights as well as on the work with patent rights within the scope of economic contracts on scientific-technical achievements.

PAST DECADE'S AID FOR DEVELOPING COUNTRIES REVIEWED

Liberal-Democratic Daily's Summary

East Berlin DER MORGEN in German 11-12 Oct 80 p 3

[Unattributed report: "Infrastructure and Industry: Main Focus of Our Trade With Developing Countries." A translation of the East Berlin EINHEIT article cited below follows this report]

[Text] GDR trade with developing countries has tripled from 1970 to 1979 and has thus developed faster than foreign trade at large, the major weight placed on installations and equipment for infrastructure and industrial development. GDR turnover with developing countries in 1979 came to a total of just about M 10 billion.

These data were supplied by the most recent edition of the journal EINHEIT, which submits a number of revealing facts: Approximately 39,000 citizens from developing countries during the period referred to got vocational training and advanced training in the GDR; roughly 10,000 graduated from our universities and technical schools; 2,300 spent time as patients in the GDR, many of them wounded persons from the ranks of the liberation movements. In turn, the GDR made possible the training of another 55,000 young people in their own countries, sending annually 300 members of friendship brigades, and in the period referred to 15,000 specialists, into developing countries.

In solidarity donations, the FDGB and the Solidarity Committee of the GDR have provided services at a value of more than M 1.4 billion since 1970. Humanitarian aid and charity during the same period came to just about M 65 million, of which the German Red Corss provided more than 35 million.

'EINHEIT's' Facts, Figures

East Berlin EINHEIT in German Vol 35 No 10, Oct 80 signed to press 11 Sep 80, pp 1081-1082

['Facts and Figures' report by Dr Siegfried Buettner, sector chief, SED Central Committee: "GDR Aid for Developing Countries"]

[Text] The trips by party and state delegations headed by SED Central Committee General Secretary and GDR State Council Chairman Erich Honecker to African and

Arab countries have contributed to developing our alliance relations with the progressive states at new dimensions and qualities.

Economic and Scientific-technical Cooperation

True to our internationalist policy, the GDR's confident cooperation with the states of Africa, Asia and Latin America has steadily been further developed in recent years. Examples of it are the GDR's friendship and cooperation treaties with Angola, Mozambique, Ethiopia and the People's Democratic Republic of Yemen. Above and beyond that, many agreements were made with these and other developing countries on economic, industrial and scientific-technical cooperation. Between 1 January 1970 and 31 December 1979, the GDR concluded 141 government agreements with 59 developing countries. They included 58 trade agreements, nine payment agreements, 27 agreements on scientific-technical cooperation and 47 agreements in the fields of economic, scientific and industrial cooperation. To implement these agreements and strengthen our cooperation, a total of 15 joint economic commissions have been set up since 1970 between the GDR and those countries.

The GDR's economic and scientific-technical cooperation with the progressive Afro-Asian and Latin American states serves the consolidation and further development of the socioeconomic construction in those countries, the support of those states' desire for a new international economic order on an equal, democratic foundation, the protection of their sovereign right to the use of their own natural resources, and the support of their struggle for economic independence and against imperialism, neocolonialism and reaction.

Compared with 1970, the GDR's foreign trade turnover with developing countries has more than tripled. In 1979 it came to 9,591 million valuta mark. The GDR's foreign trade turnover with the developing countries has grown faster than the GDR's overall foreign trade turnover.

In its deliveries and services the GDR concentrated in particular on supplying installations and equipment for the infrastructure, especially for the transportation and communication systems, for electrification, construction material production, the textile industry, machine building, the printing trade and the processing of agricultural products. Since 1970 the GDR has completed more than 650 projects in developing countries, 53 of them in 1979 alone. The GDR set up more than 100 small-trade enterprises in Vietnam and Laos alone.

Training and Dispatching of Personnel

In the consolidation of political power and the struggle for economic independence, in industrialization and the development of a modern agriculture, and in the development of the infrastructure and of new democratic foreign trade relations, increasing importance attaches to vocational training and advanced training for citizens of developing countries and to the training of university, technical school and leadership personnel from those countries.

Since 1970, the GDR has provided circa 39,000 citizens of developing countries, 9,000 of them in 1979 alone, with vocational training and advanced training, principally in such areas as farm technology, crop and animal production, health,

health and labor safety techniques, the building trade, metal working, finance and industrial management. In the same period circa 10,000 citizens from those countries attended a university or technical school in the GDR. In 1979 alone, 2,650 citizens from developing countries completed their university or technical school studies in the GDR.

The fields in which training and advanced training were provided included technology, the natural sciences, medicine, education, agriculture, the cooperative system and industrial management. In connection with the establishing of installations and the supplying of means of agricultural production, approximately 55,000 citizens of developing countries were trained between 1970 and 1979 in their own countries, 23,000 of them in 1979 alone.

This development is supplemented by our dispatching GDR specialists to those countries. Within the scope of relevant government agreements and in connection with our deliveries in installations and equipment, circa 15,000 specialists--technicians, agricultural experts, scientists, physicians, pedagogs and other specialists--have operated in developing countries since 1970. In 1979, there were 2,200 GDR specialists working in those countries. The friendship brigades dispatched by the FDJ enjoy high recognition. More than 300 young people have since 1977 been operating, mainly in Afro-Arab countries, each year.

Solidarity Donations

The services of the FDGB and of the GDR Solidarity Committee have been an inseparable component of the GDR's cooperation with the progressive Afro-Asian and Latin American states and the struggling national liberation movements. From 1970 to 1979, the FDGB and the GDR Solidarity Committee donated more than M 1.4 billion. These donations by the GDR working people have financed care shipments of different sorts including clothes, foodstuffs, baby food, medicines, study and instruction materials as well as medical care for citizens of developing countries. Over M 300 million was spent on that in 1979.

Humanitarian aid and charity given the developing countries and their liberation movements by the GDR is something that occupies a solid position. Between 1970 and 1979, that alone came to M 64,493,225. The German Red Cross of the GDR had a share of M 35,743,300 in this aid. During the same period, 2,300 patients from developing countries, many members of national liberation movements engaged in struggle among them, received free medical care in the GDR.

Solidarity in word and deed continues, as it is deeply rooted in the thoughts, sentiments and conduct of our people. In shaping its alliance relations with the developing countries and militant liberation movements, the GDR lets itself be guided by the thought that the peoples' anti-imperialist and antineocolonialist struggle is an inseparable component of the worldwide struggle for the safeguarding of peace in all regions on the earth and for the national and social liberation of the peoples in Africa, Asia and Latin America.

THIRD QUARTER ECONOMIC RESULTS PUBLISHED

Budapest NEPSZABADSAG in Hungarian 12 Nov 80 p 10

[Text]

1st to 3d Quarter, 1980
(as a percentage of the corresponding period of the preceding year)

Socialist Industry	
Volume of gross production value	98.0
Employment	97.1
Gross production per employee	100.9
Average monthly wage including supplementary payments	103.1
Construction Industry	
Construction industry output	96.5
Number of employees	95.8
Average wage of employees including supplementary payments	106.1
Foreign Trade (at current prices)	
Imports	98.9
Exports	104.9
Retail Trade Turnover (at current prices)	111.0
in particular:	
food and nonessential beverages and tobacco	110.8
clothing	106.0
miscellaneous industrial goods	112.9
Procurement	103.2
in particular:	
plant products	107.1
live animals	101.1
animal products	100.9

Performance of Transportation Enterprises

Freight transportation (in freight ton km)	100.5
Long distance passenger transportation	101.0
Cash receipts of the population from central sources	109.5
Consumer Price Index	111.0
of which:	
1980 price changes	102.4

According to data from the Central Statistical Office, the level of industrial production and sales in the first three quarters of 1980 was slightly below last year. Trends in the sales of industrial products developed in accordance with the plan's goals. The volume of foreign trade sales and deliveries to wholesale and retail trade each grew by 3.4 percent. Sales for investment purposes declined by 12.6 percent and sales for production purposes were 5.8 percent lower than a year ago. The number of industrial employees declined at a more rapid pace than calculated, by 47,700 or 2.9 percent relative to the same period a year ago. The decline in employment was especially pronounced in the light industry and machine industry. Production per employee was 0.9 percent above last year's level.

The output of the construction industry declined, in accordance with the plan. In particular, the output of state construction enterprises was lower than a year ago; construction by cooperatives was essentially the same as last year. As a result of the slowdown in investment activity, the greatest decline occurred in the civil engineering industry (7 percent), but it was also quite substantial in architectural engineering (3 percent). Specialized and assembly activity rose slightly. Construction industry employment was 14,300 or 4.2 percent less than in January-September of last year. Output per employee rose 0.7. percent. Almost 45,000 residences were completed nationwide in 9 months: this is 4.3 percent above last year's level.

Purchases of plant crops in the first 3 quarters of 1980 were 7.1 percent above the first 9 months of last year. This was mainly the result of increased sales of wheat and rye. Purchases of fruits and vegetables were lower than last year. Sales of hogs and poultry rose while sales of beef cattle declined.

Cash receipts by the population from central sources were 9.8 percent above the January-September 1979 level. Income supplements related to the price measures introduced in July of last year also played a role in this increase.

Retail trade turnover rose at current prices and remained unchanged at comparable prices relative to a year ago. The volume of retail turnover of food and nonessential beverages and tobacco is approximately 2 percent above the level at this point last year while catering industry turnover is 4 percent lower. Sales of clothing and miscellaneous industrial goods were the same as a year ago.

109.9 billion forints were spent on investment by socialist organizations in the first 3 quarters of 1980. At current prices this is 9.2 percent less than in the same period of 1979. (The decline in investment is in line with the plan guidelines). Investment spending on state controlled projects was 7.1 percent below last year while spending was 10.9 percent less.

PROGRESS IN INDUSTRIAL RESTRUCTURING NOTED

Budapest NEPSZABADSAG in Hungarian 5 Nov 80 p 10

[Article by Mrs Ferenc Nyitrai, chairman of Central Statistics Office: "On the Road to Modernization of Industrial Structure"]

[Text] Modernization of the structure of the national economy and, in particular, industry, is one of the most important factors in improved efficiency. The 20 October 1977 resolution of the MSZMP Central Committee on this issue defined the direction and most important methods of change. A mere 3 years have passed since the resolution. The first of these, 1978, was still a year of instilling new attitudes, trying out new methods and comparing our existing product structure with that of similar or more advanced countries. A number of our large enterprises carried out such comparisons, leading to results that will be useful in the years to come. At the present time, in the closing months of the Fifth Five-Year Plan period, we are in a position to survey the road we started on, the progress we have made and the opportunities and tasks facing us.

The First Phase of the Work

The pace of product structure changes is variously evaluated by many people. Enterprise professionals who are most intimately involved with the task often tell us of rapid change as soon as the preparatory work gets beyond prototype acceptance and pilot production, but the change is hardly perceptible when we look at statistics. The public at large and consumers consider the pace of change sometimes excessive when they are unable to find familiar domestic products in retail shops because production was stopped due to "product change" and no replacement is available. In fact, structural transformation is a long process. We are now in the first phase when progress is also helped by the price mechanism introduced this year.

The international experience with structural transformation shows that the process of technological innovation in advanced industrial countries during the 1960's was accompanied by an increased role of research and development intensive sectors. A look at the data for countries belonging to the Organization of Economic Cooperation and Development (OECD) shows that their production and foreign trade were concentrated in sectors which fully utilize the fruits of research and development. This was accompanied by strong specialization in the production of investment goods, increased proportion of high quality, automatic products creating new

demand in the area of consumer durables, appearance of more electronic products in markets and increased percentage of valuable products, incorporating more human labor in the chemical industry.

These trends may also be seen in the changes happening in our country.

Within the extracting industry, growth in bauxite mining output was above average. This is undoubtedly beneficial in terms of the opportunities for extracting and utilizing our domestic raw material reserves.

In the machine industry, the output of telecommunications and vacuum technology grew at an above average rate, with the overwhelming majority of products satisfying the criteria set by the system of technical and economic requirements pertaining to product shift inasmuch as they incorporate the results of domestic research and development or purchased licenses, their added value is high, most of them can be sold on favorable terms even under increasing international competition and they satisfy increased domestic consumer demand. The output of the instrument industry also grew more rapidly than the machine industry average in 1979. This activity slowed down during the current year.

Calculated at comparable prices, the instrument industry and telecommunications represented 22.8 percent of total machine industry output in 1975 while employing 28.8 percent of the total machine industry work force and 22.2 percent of its productive fixed assets. In 1979 these two sectors, considered dynamic even on an international scale and relying on adequate domestic conditions, produced 26.3 percent of total machine industry output using 31.2 percent of the machine industry work force and 24.5 percent of productive machine industry fixed assets.

It is well-known that over the last decade the growth rate of our chemical industry output was more rapid than the average for industry as a whole: the chemical industry was also one of the leading industrial sectors. In 1979, output grew at a slower rate than before and an important structural change took place in the chemical industry. This year is highlighted by a 3.5 percent growth in pharmaceutical production while the output of the chemical industry as a whole in the first 3 quarters remained approximately at last year's level. Within the chemical industry, the production of plastics is increasing at a rapid rate every year. 294,000 tons of plastic were produced in 1979, i.e., 38.1 percent more than in 1978. Production grew by another 10.2 percent in the first 8 months of this year.

In the light industry, structural change took place in sectors which were able to adapt flexibly to rapidly changing fashions. One such sector is the silk industry. While in earlier years the product scale of the silk industry was not very competitive in more demanding markets, and in fact was unable to fully satisfy domestic requirements, in more recent years it came out with a number of new, modern, competitive products based on a successful combination of various raw materials which can be marketed on much more favorable terms. As a result, silk industry was able to increase its output by more than 10 percent in the first 3 quarters of this year while the production of silk materials made from synthetic fibers increased by almost 18 percent relative to last year.

In line with international trends, an increasing percentage of agricultural products is being delivered to domestic and international markets in the form of processed food industry products. The percentage of processed foods and consumables now represents 8.3 percent of the output of state-owned industry. The role

of traditional milling industry is declining within food industry as a whole while the role of milk processing, meat, canning and brewing industries is increasing. As a result, production and export of poultry, bone-in raw meat and various types of sausages is increasing every year while the production and output of safflower seed oil is also growing at a rapid rate.

The Direction of Product Change

Transformation of the industrial product structure has also begun. Of course, rapid adaptation to changing demand is easiest in the processing industry where there are a number of examples indicating the start of a process of renewal. For example, aluminum foil is a popular product of the aluminum industry. In 1979 our production of aluminum foil grew by 50 percent relative to last year; rapid growth continued this year.

Production of a number of uneconomic products has been stopped in the machine industry while the volume and percentage of some up-to-date products has increased. These changes are reflected in the following statistics:

Production of Certain Machine Industry Products (percent)

Name of Product	1978/77	1979/78	1st half of 1980/ 1st half of 1979
Elevators, total	104.0	110.9	113.1
Semi-automatic lathes	71.0	205.6	184.6
Automatic lathes	18-fold	106.8	156.5
Program controlled lathes	80.6	376.0	248.8
High precision lathes	42.8	258.9	106.0 a)

a) based on production by KGM [Ministry of Metallurgy and Machine Industry]

There has also been some realignment within the product groups included in the table, mainly as a result of adjustment to foreign market demand. Similar trends are appearing in the production of a good number of consumer goods. For example, demand for high capacity refrigerators produced under license is growing especially fast. As a result, production of refrigerators was up 9 percent in the first 8 months of the year, compared to last year. There is increasing interest in color television sets: production from January to August of this year was up by 88 percent relative to last year. Production of stereo record players in the first half of the year was 84 percent above last year's level. Production of computer and control technology products also grew at an above average rate.

Development of new, up-to-date products often requires technological modernization. This is indispensable in the case of products which compete with similar goods produced by other countries in foreign markets and in areas where cost savings and acceptable prices are predicated on modern technology. Another important consideration is to ensure that new products are more energy efficient in order

to encourage consumers to replace obsolete machines and appliances. There are some good examples of this: new models of black-and-white television sets are more energy efficient.

Another favorable sign is a significant decline in the use of imports in implementing product change: this trend is continuing this year. Credit measures aimed at import savings are also helpful in continuing toward this goal.

The Percentage of Unskilled Workers

Finally, positive changes may be seen in the area of the most important cost: manpower utilization. In the beginning and middle of the 1970's the use of auxiliary and, in particular, unskilled workers in industrial production was very high. Even as late as September 1976, the number of employees performing unskilled work represented 14.1 percent of all blue-collar employees within socialist industry. By September 1979 this ratio declined to 11.5 percent. In contrast, the number of employees performing skilled work increased from 46.7 percent to 50.1 percent. This change is occurring in almost every branch of industry. For example, the number of unskilled workers in the machine industry declined from 10 percent in September 1976 to 7.8 percent in September 1979. Still, we have considerable reserves in the area of efficient manpower utilization, as shown by the slow rise in industrial productivity during this year; we are still significantly behind countries of comparable size and level of development.

Thus, promising trends toward structural change are visible in production and related aspects of material, energy and manpower utilization. The present conditions of economic regulation contribute to the acceleration of this process and exemplary activity by enterprises ready to take the initiative may further accelerate progress.

GROWTH IN EXPORT OF ANIMAL PRODUCTS NOTED

Budapest MAGYAR MEZOGAZDASAG in Hungarian, Nos 43, 44, 22, 29 Oct 80

[Article by Mrs Istvan Benda: "The Export of Animal Products Is on the Increase"]

[22 Oct 80 No 43 p 21]

[Text] TERIMPEX [T. Foreign Trade Enterprise of Livestock and Crops] is one of the most important enterprises of the Hungarian economy for generating capitalist exchange. The animal products it handles are the result of the work of tens of thousands of men in agriculture and the food industry, and for decades it has produced about one-fifth of our income from capitalist export.

Our country is among those practicing intensive livestock husbandry and there are few countries in the world delivering to foreign markets such a large fraction of 4 branches of animal husbandry products as ours: 45 percent of cattle, 20 percent of swine, 90 percent of sheep and 65 percent of dressed fowl.

Our annual export of animal products (live and slaughtered) is between 350-400 thousand tons amounting to about 4 percent of all of the livestock and meat reaching international markets. This is an outstanding ratio in comparison to our animal stocks.

The year 1980 started favorably with respect to the possibilities of international trade. However, it appeared that much less product would be exported than the year before and a dollar income exceeding that of the previous year would be possible only by sharply raising the prices. In response to various measures aimed at increasing the amount of production and purchase, it became clear already by the second quarter that we would be able to export more than projected earlier in the year and the income--in forints--would exceed the 1979 income at least by 4 to 6 percent.

The results of the first half of the year provide a basis for estimating the anticipated annual export trade. In forints, our achievements were 12.5 percent higher than during the first half of last year.

Only Good Quality Beef Cattle Can Be Sold

During the first half of the year, only about half of our last year's export could be delivered from beef cattle. The types of available product were

rather mixed. It contained a rather high percentage of crossed (example: Holstein-Friesian x Hungarian spotted varieties, in general less favored by our markets. In spite of this our selling prices, in dollars, were increased by 20 percent.

We succeeded in raising the beef export by 30 percent but this was not enough to completely balance the loss in beef cattle. Considering the price increases, beef cattle and beef export amounted to one-fourth of the capitalist export trade organized by TERIMPEX during the first half of the year. In spite of the considerable decrease in the amount of goods, this produced only 4 percent less income to the national economy than last year.

The prospects for selling products of the cattle branch are in general very good: purchase is not hindered by customs of consumption; moreover, cash-based demand for it is expanding. In addition to already existing markets, we could involve new countries in the trade if more products suitable for export would be available.

Outstanding Marketing Possibilities

Our sheep export produced exceptionally good results last year. Both amounts and prices were raised to an extent never before seen. This represented 45 million dollars in export income. Compared to the first half of last year, the average weight of the exported animals was lower this year and there was an increase in the ratio of suckling lambs which could have been developed into a fattened product by the second half of the year.

The income of producers was considerably lowered by the drop in the value of the Italian lira. Even raising the export prices could not balance the unfavorable exchange rate.

The marketing possibilities for products of the sheep branch are outstanding.

Based on the results of the first half of the year, the expected--in general not worsening--market conditions, and the amount, composition and quality of goods available to us during the second half, we can expect our annual accomplishment to be outstanding in the history of TERIMPEX. However, both in the production of live animals and in the course of industrial processing, every producer must pay maximal attention to the demands placed on export goods.

Twice the Amount of Pork to Western Markets

We exported 20 percent more live swine and doubled our deliveries of bacon sides and cut-up pork to capitalist markets. The export of these products amounted to about 27 percent of the dollar income of TERIMPEX. This noteworthy achievement was due not only to increased quantities but also to price increases. Making up the highest ratio of goods, the price of pork sides could be raised to a level not seen since the memorable Europe-wide scarcity of pork in 1976. The excellent timing of marketing also played a considerable role.

Pork products can be marketed to a much more limited market than those of cattle. Swine on the hoof almost exclusively, can be sold only to the Soviet Union or to another socialist country which happens to be struggling with a pork scarcity. Pork sides primarily serve to satisfy the demand in the Soviet Union. The Western countries are self-sufficient, and conditions arise only occasionally--for instance in Italy and France, in some years also in Spain and Greece--under which they can pay us favorable prices.

Of products of the swine sector, processed pork--chops, spare ribs, fresh ham, shoulder with or without bone--can be easily and regularly sold to West European countries. We are trying to exploit this possibility by means of the increased productivity of new meat processing plants.

During this half year, there was a 10 percent increase in the export of dressed fowl and a 20 percent increase in income compared to 1979. We hope that the results of this year will contribute to the recovery from the unfavorable effects suffered by this branch in 1978 when, because of bad international marketing conditions, lower prices and the accumulation of unsold goods caused great losses to the fowl processing plants and also had a negative effect on the will to produce by the agricultural enterprises and the household plots.

We closed a successful 6 months in the export of goose liver, hare and fish. Among dairy products, butter should be emphasized since it has increased considerably this year and good world market prices have developed.

[29 Oct 80, No 44 p 21]

[Text] On the occasion of this brief accounting, it might be useful to summarize those tasks which the growers and all those who influence food production ought to consider in the interest of successful export in the coming years.

Beef Cattle: The Soviet Union Is the Largest Purchaser

Earlier--before 1974--more than 90 percent of our export went to Italy. This consisted almost exclusively of Hungarian-brindled young steer which fetched a good price because they were rated as outstanding quality. Since then, both the ratio of the market and the absolute amount of export have fallen back and, within the latter, the purebred Hungarian brindle products have decreased.

We still have goods in small amounts originating from the crossing of Hungarian-brindled with [du] limousin [a French breed of steer] or with charolais (meat type). These fetch the highest price followed by goods from Hungarian-brindled cattle. Since the export is divided approximately as follows: 40 percent to Arabic, 20 percent to Italian markets and 40 percent to the Soviet Union, the demands of these markets are described in the following.

Italy: Hungarian-brindled cattle with a minimal weight of about 550 kg are the most sought after. The Hungarian-brindled x [du] limousin crossbred cattle fetches $150-200 more per ton while the Hungarian-brindled x Holstein-Friesian F_1 young cattle can be sold for about $150-200 less, occasionally and only in small quantities.

We can find buyers at a comparable price for Hungarian-brindled crossed with Herford young steers with a weight of only 450-480 kg, because it is still not too fatty. Purebred Hereford is not marketable because of its high suet content.

The Italian buyer wants uniform prices and prefers cattle from large-scale enterprises (agricultural cooperative or state farms).

The Soviet Union wants slaughter steer between 500-560 kg weight, fattened in stables. It pays a good price for Hungarian-brindled cattle raised on household plots and is willing to buy the Hungarian-brindled x Holstein-Friesian F_1 crossbreed for $100 less per ton.

Libya is the only noteworthy market where we can deliver 30 to 40 percent Holstein-Friesian x Hungarian-brindled F_1 products. However, because of considerable--mainly Irish--competition, it [Libya] has limited demand for the Hungarian product.

Lebanon is almost mostly interested in Hungarian-brindled cattle; The 450-480 kg weight Hungarian-brindled x Hereford F_1 can also be marketed [there] in smaller amounts, be they stabled or pasture animals.

Sheep Branch: More Attention to Quality

In the opinion of specialists, because of the high export prices prevailing for several years, a negative selection has been practiced on the farms. Good quality, outstanding stock was exported and the lesser quality was often retained for breeding. As a result, the Hungarian combed Merino can be termed obsolete today because it tends to become fatty at a relatively low weight.

With the size of animal stock Hungary has, an increase in the export income of the sector can only be achieved by increasing the rate of reproduction and the average weight. Young lambs should be exported to the least possible extent; at the most, 10-12 percent annually and preferably the females--of course, the problem of selection ought to be worked out. Fattened, these are not accepted at all by our markets or are accepted as only a small fraction of the total, and the price is decreased by 5-7 percent. Rumania and Poland, two much larger sheep exporting countries than we are, will hardly or not at all export young lambs.

The "express lamb" should preferably be fattened to an average of 30-32 kg. It would be best if stock under 30 kg would not at all be sold to the purchasing companies because, for livestock shipped over greater distances, we have to allow for 10-12 percent losses. In the case of 30 kg lambs, this represents 27 kg in purchase weight. However, if stock between 27-30 kg is purchased, it would be very important to segregate these because higher prices can be gotten for this cateogry than the bulk price for stock weighing 27-35 kg each.

Recently, the importance of Arabic markets has increased. These countries and also the GDR and Belgium expressly demand heavier (35-40 kg) goods and pay a good price for them. Based on data from our partners in production, we calculated the profitability of fattening. It was shown that fattening to weights higher than done currently would also considerably increase the profit of the producer.

Swine Branch: More Uniform Products

Much more uniform products are produced for export today from domestic swine stocks than a few years earlier. Nevertheless, quite a bit of undesirable crossbreeding still occurs producing a so-called pigmented swine, which is not expressly a meat producer. The pigmented swine is unsuitable for the production of unskinned products (for example of our frequently exported Parma ham) even if it has an adequate bacon layer or fat content.

The 110-115 kg weight swine is desirable for live export. The 95-105 kg swine is suitable for the production of pork sides with bacon, the 105-120 kg swine is good for the production of processed pork sections although, in some cases already at this weight, the characteristics of the strain and the feeding method may produce a thicker layer of bacon and more fat content than desired by our markets (for instance, bacon thickness can be no more than 3 cm). Among others, this has the result that the Hungarian lean bacon has more fat than the Western markets are used to and relatively small amounts of it can be sold.

Fowl Branch: Continued Price Fluctuations Must Be Expected

To satisfy the quality and weight demands of foreign buyers, live fowl must definitely be delivered to the purchasing sector within the following weight limits according to types: chicken 1.35-1.50 kgs, turkey 4.20-4.50 kgs, guinea fowl 1.30-1.40 kgs, roasting duck 2.40-2.60 kgs, and roasting goose 4.20-4.80 kgs.

Because of future fluctuations in world market prices, even though within narrower limits, to reduce fodder expenses it is especially important to decrease the amount of fodder needed to produce 1 kg meat.

Every producer must also know that there are limits to increasing production dictated by the possibilities of selling on foreign markets which must be adapted to. Otherwise we are faced with plummeting prices and unsold stocks.

In general, production increases (according to the prevailing, specific contracts with the buying sectors) are possible for the most widely marketable chickens. Only a negligible expansion in the export of other types of fowl is possible because

--geese and ducks are demanded by only certain markets and in limited amounts. The producer circle is traditional and no one else can take over in the case of increased exports;

--turkeys are produced and consumed in large amounts worldwide. Their share on the world trade is minimal and competition is fierce;

--the production of fattened geese livers and the possibilities of expanding the liver export are limited because such geese can only be sold to limited markets. If the goods are low in fat, some of them can be sold dressed to capitalist countries. However, there is no way to try to double the goose liver export.

After having produced the products in the desired weight range and at a suitable time, the possibilities of marketing are, of course, very much influenced by good management of processing and export.

SITUATION OF INCOMPLETED INVESTMENTS DISCUSSED

Budapest FIGYELO in Hungarian No 45, 5 Nov 80 p 7

[Article by Dr Peter Keresztes: "Background to Incompleted Investments"]

[Text] Among the statistics of the past decade we will not find many columns which show an almost threefold increase in 10 years. Among these few are incompleted investments, which have increased with particular rapidity in the first 4 years of the Fifth Five-Year Plan. From a distribution of sources point of view, the economists and economic politicians explain this unprecedented climb of incompleted stocks, which are evident as "frozen assets," basically by the increase in the average magnitude of the investments, the lack of organization in savings and investment activity, the fragmentation of implementation capacity, and in the final analysis the tensions of the investment market.

This reasoning is appropriate to the past decade, but to a certain extent one sided. Its starting point is the outlook that regards incompleted investments merely as "frozen assets" and does not consider that at the same time it is the prior condition of the incompleted investments. We can carry out effective and even investment activity only in case of incompleted investments of appropriate size and structure.

Not Only Frozen Assets

The concept is growing stronger both in economic literature and practical economic policy that investment policy should concentrate not merely on the annual investment outlays and the purchasing power related thereto, but must also regulate the series of individual investment decisions by striving to assure a steady balance on the investment market.

Without trying to be complete, I shall introduce in the following some methods related to incompleted stocks, the use of which would help in the effective guidance and planning of the investment process, and an appropriate influence on decisions.

It is foreign to an outlook which concentrates not only on annual outlays but on the investment process as a whole to approach the problem of incompleted investments by relating them simply to annual achievement. Such an approach makes sense only if we regard this ratio as the starting point for estimating average realization time. Unfortunately, this has not been the practice up to now. At present

the majority of the economists as well as mass communications grade the investment situation according to how the ratio of incompleted stocks and annual expenditures is developing. We need a deeper analysis before forming a value judgment. For example, a decline in the above-mentioned ratio may in itself represent a big investment upswing, or its conclusion.

I am convinced there is no absolute index which could grade the global magnitude of the incompleted investments, but the following method, which is still not widely enough employed, can be used more consistently for orientation than by relating to annual achievement.

Let us assume that there are enough investments in process for us to state that the total cost estimates of investments at the 1 percent and the 99 percent degree of completion are the same, and the same is true of the 2 percent and the 98 percent investments as well, and so on. Consequently the average degree of completion of the investments is 50 percent. And thus a total of one-half of the cost estimates for the investments in process has been expended on the investments thus far. We still need to know the volume of parts in operation, which is frequent particularly in the case of large investments. According to various calculations, these investments in process make up about 30 percent of the cost estimates.

A Possible Yardstick

Thus we can calculate the desired magnitude of incompleted investments by deducting the value of the parts in operation, that is, parts which are already a completed investment, from one-half of the cost estimates. Following the 1978 example, the calculation is as follows: at the beginning of the year the total cost estimate of all the individual investments with a value over 5 million forints came to 710 billion forints in round numbers. Putting the vaoue of parts in operation at 30 percent, the "desired" incompleted investments (710 x 0.5-213) is 142 billion forints. On the other hand the observed incompleted investments of the socialist sector is 175 billion forints, more than 20 percent higher.

I shall note that this calculation in itself cannot form the basis of some kind of value judgment. Its advantage is that it is better than the earlier practice of relating to annual payments, and it can be the starting point or the supplementary method for further analyses. On one hand, neither the data nor the estimate procedures are exact in calculation. With the development of the statistical information process which follows the investment process, it may be assumed that at the same time the calculations from this point of view will become more reliable. On the other hand, even behind the globally optimum, "desired" magnitude of incompleted stocks gained as a result of possibly exact calculations, there may be serious structural tensions which will later disturb the process.

For this very reason, in my opinion, we also need further examinations at least according to decision category, material-technical composition and economic branches. It is not my goal now to describe the implementations in detail or to review the results, but let me give several interesting examples from past experience.

The incompleted stocks of domestic machinery investments is essentially the same size as the similar index for import machinery. At the same time, in the last

decade the change of incompleted stocks of import machinery, in absolute value, exceeds the similar domestic figure. On basis of the relationship between the Five-Year Plan and the investment decisions we can arrive at the conclusion that the nonsocialist machinery deliveries are closely linked to contracts signed on the basis of investment plans. The same can be said of socialist imports. The investments are generally delayed, and therefore these machines cannot be put into operation for a long time. At the same time the domestic machinery deliveries are better linked to the actual completion of investments, and to actual creation of the machine receiving capacity.

The result is that it is the capitalist import machinery, which represents the greatest burden to the economy, that stands idle for the longest time, waiting to be fitted in. We will be able to reduce losses to the minimum in the future if the construction and machinery aspect of realizing the investment proceeds in a coordinated way, and we are ready to receive the capitalist machinery imports and put them to the earliest use possible by technical parameters.

It is evident from the accompanying graph that 1979 was the first year in the decade when the growth in the incompleted stocks of import machinery was smaller than the similar index for domestic machinery. This was apparently caused not only by the decline in imports but some improvement was already evident on the investment market and thus the organization of investment activity also improved.

Graph. Changes in the Incompleted Investments of Socialist Organs as Compared to the Previous Year (in billion forints)

Tensions in the Parts

The other example is to be found where branch and decision category tensions are concealed behind the economic index for incompleted investments. For example, the changes of incompleted stocks in industry can be linked with the Fifth Five-Year Plan, but this is counterbalanced somewhat by other economic branches, and thus the interrelationship at the economic level can hardly be shown. A similar

example is the following: in the Fourth Five-Year Plan period the increase in incompleted stocks changed in a contradictory manner. On the other hand, the economy's incompleted investments are outstandingly high for 1977, and its increase of about 24 percent can be ascribed to the fact that by the means of various economic political constructs we forced the enterprise investment decisions as well to travel a path similar to that of state investments.

As a result of the regulation which brought about a restrained investment decision activity in the past two decades, this year will see an end to the increase of incompleted investments at a high level, and even something of a decline may occur. This in itself favorable phenomenon, however, also calls attention to the fact that those who guide the investment process must avoid the development of a situation where investments are in process for the most part at a low completion level, and it becomes impossible to put them into operation at a desired and even level. On the other hand, the development of the above situation can be avoided, the development decisions must be kept in a channel that will hinder the development of the investment cycle.

Perhaps it can be felt that in this article I was not only seeking to call attention to an unjustified distortion of the importance of incompleted investments. At present, the most important task in investment policy is the effective regulation of the process in harmony with our economic political goals as realized through individual investment decisions. This would also have an advantageous effect on the magnitude of the incompleted investments. At the same time, a deeper analysis of the latter category could also provide useful information for those responsibly interested in the guidance of the process.

NEED FOR INTENSIFIED LAND RECLAMATION STRESSED

Warsaw DZIENNIK LUDOWY in Polish 4 Nov 80 p 3

[Article by Franciszek Nasinski]

[Text] If we do not produce the amount of grain needed by our country ourselves, we must supplement our own production by importing grain. Farmers in the United States or in Canada can produce grain for us. This is what is happening now. Of course, we must pay for this grain. If we do not have ready cash, we buy on credit. Then we must add the interest on the negotiated loan to our outlay for the grain purchase.

We have imported grain for many years. Recently our imports have risen alarmingly to more than 8 million tons of grain and fodder yearly. The capital outlay for this purpose amounts to $1.3 billion a year. Grain is becoming more expensive.

Grain purchased abroad must be transported across the ocean, we must pay the freight and insurance charges, it must be unloaded in Polish ports and then it must be transported to mills and fodder plants, and from there it must be taken to its destination, i.e., Gmina Cooperative (GS) warehouses. The costs keep mounting. Would it not be simpler and cheaper, instead of transporting imported grain to, let us say, the Wloclaw and Suwaly voivodships, to produce it and process it into fodder on the spot?

There are many reasons why our grain imports, instead of declining, have increased. One of these is the price paid to Polish farmers for their grain. It is more profitable for farmers to cultivate grain and then use it for fodder on their own farms than to sell it at GS purchasing centers. There are also extraeconomic causes imposed by the system.

A major factor in agricultural production, besides man--his dilligence, resourcefulness and ingenuity--is the earth. There are situations--which are by no means extraordinary--in which even an increase in mineral fertilization will not bring about the desired increase in grain harvests. This increase is contingent upon the regulation of water ratios. If the construction of protective embankments along rivers and the possibility of draining excess water from precipitation are not considered in time, then, as was the case last year, all of the farmers' outlays will come to naught and their work will be of no avail.

The regulation of water ratios, including the drainage of arable lands, is thus a necessary condition for progress in agriculture. Outlays for land reclamation are costly, without a doubt. But importing grain is even more costly, not to speak of the dependency of the state on foreign nations in such a basic matter as feeding the nation.

Grain harvests on drained lands show an increase of 10 to 15 quintals per hectare. During wet years drainage is the decisive factor for harvests in general. Experts calculate this year's losses as a result of flooding caused by an excess of precipitation water at 20 billion zlotys. On the other hand, outlays for land reclamation this year, together with expenditures for supplying villages with water and for construction in this area, amount to 12.8 billion zlotys. A comparison of the two figures is shocking. They represent a very strong argument for increasing outlays for land reclamation and for the expansion of the range of efforts to regulate water ratios on lands in use.

Outlays for land reclamation during the 10-year period now coming to a close increased on the financial score. However, as a consequence of price and cost increases their range was narrowed. Experts have cried out in protest against this situation. Farmers have brought up this issue many times. However, as Majakovsky said, their voices were barely a squeak.

Thus the scope of such efforts narrowed at a rapid rate. In 1968, 215,000 hectares of arable land were reclaimed in general; in 1976--194,000 hectares, and last year scarcely 90,000 hectares were reclaimed. The figures with regard to drainage are the following: 164,000 hectares in 1968, 146,000 hectares in 1976, and 84,000 hectares in 1979. With regard to land reclamation efforts on grassy lands in use the decline was even more drastic. The figures for the same years are respectively: 120,000; 57,000 and 26,000 hectares in 1979. A similar decline has been noted in the bringing into cultivation of grassy lands in use: from 133,000 hectares in 1968 to 55,000 hectares in 1976 and 34,000 hectares in 1979. Work on rivers and canals calculated in kilometers decreased during this period: from 1,620 kilometers to 875 kilometers to 609 kilometers last year. Embankments built against flooding decreased from 162 kilometers in 1976 to 75 kilometers last year.

We must assume that losses in grain harvests last year, by comparison to 1968, of approximately 1 million quintals, and in harvests of good quality hay of approximately 4 million quintals are the result of the decreased range of land reclamation efforts.

According to expert opinion, lands drained in the final years of the current five-year plan did not even compensate for the decline in reclaimed lands estimated at 100,000 hectares. These losses are the result of the depreciation of land reclamation equipment manufactured before World War II. This is primarily in reference to the western and northern regions of the country.

It is a fact that gradually, implemented land reclamation efforts have undergone a sharp decline. As a rule, in such cases the reason that is given is the lack of so-called processing capacities. In this case, however, the reason is a different one. This decline occurred despite the fact that the production capacity of enterprises specializing in efforts of this type was not fully utilized.

For example, enterprises joined together to form the Central Administration of Marine Construction and Land Reclamation had 866 drainage machines, with which they laid 39,300 kilometers of pipeline. The full use of this machinery could complete 60,000 kilometers and could lay 105 pieces of modern machinery for non-groove drainage. Pipeline of 80,000 kilometers in length could have been laid, but only half as much was laid.

Taking into consideration the fact that the materials-intensiveness of land reclamation construction is low--only 24 percent of investment costs--while in construction in general and in agricultural construction, materials absorb nearly half the cost, exactly 49 percent, the limited nature of outlays and of the dimensions of land reclamation cannot be justified rationally even in a period of the general reduction of investment outlays in the nation.

One of the basic factors fostering an increase in farming has been the installation of water pipelines on farms. Water in homes and barns has raised the living standard of the farm population. It has also fostered an increase in work productivity. Less time is lost on tending livestock. Farmers can grow more, because the work is easier and the lack of help does not represent an insurmountable obstacle. While it is true that the scope of efforts in this regard has not been reduced, only a small proportion of villages has water pipelines. Barely 24 percent of farms use water from pipelines of various types. Of these, 11 percent have been constructed by state enterprises, and 13 percent have been built by individual farmers at their own expense, as a rule using surface flooding waters of poor quality as a basis. This puts the Polish village in one of the lowest places in all of Europe.

A decision cannot be put off in this situation. Outlays for land reclamation guaranteeing a real increase in implemented efforts must be increased. The utilization and conservation of equipment and the land reclamation system must be improved.

In the 10-year period now ending, agriculture has received a sharp dose of properly directed programs of development and promises. Unfortunately, it has all been just talk. The situation must change. The unsatisfied food needs of the nation are exerting pressure in this direction.

FARMERS RECEIVE AID FOR PURCHASE OF MACHINES

Coupons for Potato Deliveries

Warsaw CHLOPSKA DROGA in Polish 12 Nov 80 p 1

[Article by A. Jar]

[Text] The Peasant Information Service. The poor harvest of potatoes has seriously limited their sale at purchasing centers. The purchase of eating potatoes, which are so important for supplying the market for the winter, is significantly less than projected. Given this difficult situation, the Central Union of Agricultural Cooperatives, in order to encourage farmers to sell their potatoes to meet the needs of markets in larger cities, have undertaken to tie in potato deliveries with the possibility of issuing farmers the right to accelerated purchase of farm machinery which they need.

Those suppliers who deliver extra large supplies of eating potatoes are to receive coupons for tractors and other machinery. Local authorities in individual regions will determine the minimum size of the delivery meriting a coupon toward equipment which is in short supply.

This system of rewarding large suppliers has been tried for several days in Poznan Voivodship, as well as in several others. Authorities in Poznan have determined that a farmer who wishes to receive a coupon for a tractor must supply not less than 40 tons of eating potatoes. This unusual system of incentives, which has been created under the present conditions of exceptional difficulty, has already brought results. The first priorities for potatoes purchased now are to supply hospitals, workers' cafeterias and other institutions of collective life. A portion of the total purchase goes toward supplying the populace via collective orders at places of work. These orders are much higher this year than in the past. In this way, the supplying of stores suffers. Current deliveries can never meet the need in cities, and for this reason in front of stores there are queues of people waiting to buy potatoes.

Credit for Young Farmers

Warsaw CHLOPSKA DROGA in Polish 12 Nov 80 p 2

[Article by M.D.]

[Text] Peasant Information Service. No one has to be pursuaded of the fact that for a young farmer to undertake to run his own farm is to open the proverbial

Pandora's box of troubles. The many suggestions and requests that reach the Main Administration of the Union of Socialist Polish Youth [ZSMP] attest to this fact. They refer to such subjects as the introduction of installment buying of machinery and tractors, an increase in rebates for the purchase of land, providing young couples who farm with individual credits and facilitating the securing of credit for housing construction in the country.

As a result of agreements between the Main Administration of the ZSMP and the Ministry of Finance it has been proposed that young farmers (up to 35 years of age) be allowed to purchase a tractor on credit, provided that they have been allotted one, of course. The cooperative banks will serve as creditors for up to 90 percent of the cost of the tractor for a period of 8 years at an annual rate of 6 percent. Young farmers taking over a farm or setting up a new farm will receive priority treatment for buying on credit.

In order to be considered for credit, both young couples and individual farmers must meet a set of requirements which were formerly applicable only to those employed in socialized places of work. In other words, those young couples in which one spouse is not over 35 years of age and the other is not over 40 years of age, and not more than 5 years has elapsed since the couple was married may be eligible for credit; or, those young couples in which one spouse is not over 35, the other is not over 40, and not more than 5 years has elapsed since they acquired their first independent place of residence may be eligible for credit. Persons rearing children alone are also eligible for credit, provided that they are not over 30 years of age, or 35 years of age if not more than 5 years has elapsed since they acquired their first place of residence. Young couples may also receive credit during a period of military service or study, if their parents act as co-signers. The amount of credit will be 70,000 zlotys, the waiting period will be 9 months, and the repayment period, 5 years.

Young farmers have gained significantly with regard to undertaking the construction of their housing. Previously, in order to be eligible for credit for housing construction the applicant had to make use of his own funds for 40 percent of the estimated total cost. At present, in justified cases, the cooperative bank may reduce this personal share to 10 percent. The Ministry of Finance has also proposed issuing a recommendation that the number of loans made available for housing construction in the country not be limited.

A demand submitted by young farmers for increasing a partial refund of the purchase price of land from the State Land Fund from 30 percent to 50 percent will be forwarded by the Main Administration of the ZSMP to the Ministry of Agriculture for consideration.

SOCIOECONOMIC VALUE OF SELF-MANAGEMENT, SELF-ADMINISTRATION

Bucharest ROMANIA LIBERA in Romanian 29 Oct 80 pp 1, 5

[Article by Victor Dinu]

[Text] The new economic-financial mechanism is, beyond theory, of vital importance to our development. Its application was necessitated not as a result of someone's wish but by the dialectics of the development of the productive forces and the relations of production. Moreover, in this intricate system, self-administration is a factor.

Our party's concern for the scientific organization and management of the economy has significantly increased after the Ninth Congress of the Romanian Communist Party. From then on, for 15 years, measures were constantly taken to create a modern system of economic-financial organization, management and planning. As for the democratic forms of management, even though they were specified in the same period, they rooted more rapidly and operated on an overall scale in the entire socioeconomic sphere in this country. This did not apply to our economic-financial mechanism whose components were not promptly geared to the natural changes that took place in the development of the productive forces.

This phenomenon was timely and excellently pointed out by Nicolae Ceausescu. As early as in 1977, at the general assembly of working people at the Bucharest Heavy Machinery Enterprise, the party secretary general stated: "The democratic forms of management in our economic system did not proceed at the same rate as the upgrading of the system of economic-financial management (....) Unfortunately, some economic and financial cadres find it difficult to detach themselves from what they learned in the past, from old procedures, from what no longer corresponds to the new realities in Romania. That is why firm measures are needed to organize this sector as well, to bring the economic and financial mechanism to the level of development of the new forms of collective leadership, to do away with all that does no longer correspond."

Followed the Decision of the March 1978 Plenary Session of the Central Committee of the Romanian Communist Party, of outstanding importance in specifying the goals of the new economic-financial mechanism. The requirement

of switching to a new quality of economic activity necessarily involves upgrading the economic-financial mechanism so that the economic units, their bodies of collective leadership may have the adequate leverages for best possibly fulfilling their role and duties, in order to stimulate greater economic efficiency and material incentives for working people in better utilization of exisiting resources and obtaining of superior economic results.

For the achievement of these objectives regulations were adopted such as the law on the organization and management of economic units, the law on planned socioeconomic development of Romania, the law on finances, the law on the formation, planning, appropriation, and payment of profits, the law on economic contracts, and so forth. A sound basis has thus been created for the application of the new economic-financial mechanism and also favorable conditions for the firm promotion of the principle of economic self-management and self-administration.

What actually does it mean for the economic unit to conduct its activity on the basis of the principle of self-management and self-administration? There is nothing more simple and more logical: paying its expenses from its own incomes. It means not working purposelessly, as, unfortunately, is sometimes the case, and then appealing to the state budget. Self-management means returning the sums advanced by society and actively participating in the formation of the central sources of the state. In this context, the budget of incomes and expenses, a tool on which we shall dwell again, is an outstanding factor.

In 65 days, including today, we shall enter the new five-year plan period. Are we now certain that all economic units have finalized their self-management system? If we wish to fool ourselves, our answer is affirmative. But we are realists and are aware of the actual situation in enterprises. Hence, we must state that self-management, this "gear" in the comprehensive economic and financial mechanism, is still moving rather slowly and hesitantly.

Naturally, there is the question of why are some enterprise managers delaying to organize production on the basis of the new economic-financial mechanism. Simply because the new economic mechanism requires a new, revolutionary, specific style of work. One felt better under the warm protection of overall production. Hence, responsibility, also, was on an overall plane. The new economic-financial mechanism has a merciless attitude against half-measures and red tape.

The manager of the enterprise, the collective which he heads, are assessed by the physical output and the net output, by the profits which they achieve, profits evidenced by the local budget. The collectives of working people already are familiar with the economic plan of their own unit for 1981. As is normal, the plan incorporates the basic ingredients of the budgets of incomes and expenses: the volume of output, the volume of investment funds, the level of operating costs, the remuneration fund, other financial assets for completing social projects, and so on. The rigorous, detailed implementation of the budget of incomes and expenses actually means wise management of the material assets entrusted by society to the collective involved,

it means concern for greater labor productivity, integration into the consumption rates for materials, fuel and energy. In other words, self-management means greater responsibility in work and order and discipline in all the sectors of activity.

It is clear that only in this way we can assure the harmony between socialist worker democracy and the economic mechanism, with the bodies of collective leadership in enterprises and centrals thus having the necessary tools for promoting greater economic efficiency and material incentives for working people in obtaining the best possible results.

In this context, the preparation of the budgets of incomes and expenses for 1981 is a decisive factor in strengthening economic-financial self-management. It is normal for each enterprise to create its own funds for meeting the current needs of production, for payment of work, meeting the investment requirements for expanding the enterprise and housing construction.

Undoubtedly, self-management coupled with economic-financial self-administration enables ministries, industrial centrals and enterprises -- all together and each individually -- to plan and achieve the entire output in conformance with the actual needs of the domestic and foreign markets. Now the guide no longer ought to be overall output, because we produce not for the sake of producing but for the products involved to assure the satisfaction of the real needs of production and consumption of the population and for meeting the export requirements.

Dwelling again on the budget of incomes and expenses, a basic tool for strengthening economic-financial self-management, it must assure the financial balance, which is of vital importance to all economic units. In other words, one should not reach the point of consuming more than one produces. This principle will certainly result in promoting in day-to-day work a greater drive to wisely utilizing the material and financial assets and labor. Rigorous evidence of expenses and of the results of production by the body of collective leadership will help to stimulate every member of the enterprise to work better, to be a better administrator, to make every effort for his factory, construction site to be profitable.

The question also arose whether self-management and self-administration do not contradict the basic principle of our party and state, democratic centralism. We already have many examples and practical results which prove that worker self-management and self-administration create actual prospects for the best possible fulfillment of the increased assignments given to the basic units and their bodies of collective leadership. The dovetailing of democratic centralism with the increased duties of economic units only results in greater initiative in implementing the laws and decisions taken on a central scale, for the exemplary completion of the uniform national plan for socioeconomic development of our country.

EFFORTS OF TRADE NETWORK TO SATISFY NEEDS OF CONSUMERS

Bucharest ROMANIA LIBERA in Romanian 24 Oct 80 p 2

[Interview with Ana Muresan, minister of domestic trade, by Mircea Scripca]

[Text] [Question] At the recent plenary session of the Central Committee of the Romanian Communist Party great emphasis was placed on the problems of production and marketing of consumer goods. What steps will the trade sector take to implement the tasks outlined, for the purpose of better supplies of commodities to the population?

[Answer] The proceedings of the plenary session of the Central Committee of the Romanian Communist Party held on 14-15 October 1980 marked a special point in the life of our people. In his speech party secretary general Nicolae Ceausescu made a profound, scientific analysis of the accomplishments under this five-year plan and gave the guidelines for 1981, the first year of the next five-year plan. The instructions given at the session by the party secretary general are an outstanding support to the consumer goods industry and also to trade, in guiding their activities for the purpose of better supplies of commodities to the population.

In the context of the significant achievements obtained in the overall economic growth, trade -- as an important component of the improvement in the standard of living and the quality of life -- has developed correspondingly. Compared with 1975, the sales of retail goods now are 50 percent higher and the structure of supply has continuously expanded, reaching approximately 320,000 products and brands. Moreover, the socialist trade network under this five-year plan has increased by about 2 million sq m. Department and general stores, with ample facilities for using modern marketing forms, were built in almost all Romanian counties.

The conditions ensured provide a sound basis for upgrading trade, for better meeting the consumers' needs.

[Question] What is being done during this quarter --in the fall-winter period -- to ensure proper supplies to the population?

[Answer] In the first place I would like to point out that -- as a result of the concern displayed by the leadership of our party and state -- this quarter will see an extra output of consumer goods valued at about 3 billion lei and next year will see an extra output of 10 billion lei, which will add to the existing resources and will upgrade the supplies to the population.

During this period much attention is paid to supplies of farm foodstuffs. In spite of adverse climatic conditions this year, adequate amounts are ensured in terms of potatoes, vegetables and fruit, for both current consumption and winter supplies. During the 1 September-15 October 1980 period the socialist trade units sold to the population 120,000 tons of potatoes, 181,000 tons of vegetables (onion, cabbage, peppers, and so on), 33,600 tons of fruit, and 41,600 tons of grapes. A significant factor in this area involved the organization of the "Month of Horticulture," sponsored by the General Economic Directorate of Hortiviticulture in the Ministry of Agriculture and Food Industry. The assuring of supplies continues to run smoothly. Marketing provisions for this quarter -- versus the corresponding period of last year -- envision increased quantities: by 35.8 percent for potatoes, by 32.3 percent for vegetables, and 13.6 percent for fruit. Furthermore, steps are taken to store the vegetables and fruit needed for marketing in the first half of 1981. Because there are lags in this area in some counties, the produce transportation and storage procedures must be accelerated.

Quantitative increases are anticipated in this quarter -- versus the fourth quarter of 1979 -- also for other products, such as: 14.8 percent for bread, 10.2 percent for pasta, 3.2 percent for cut meat, 30 percent for meat products, 24.8 percent for animal fats, 19 percent for canned vegetables, 13.2 percent for tomato paste, 13.5 percent for rice, and so forth.

[Question] During the cold season, also other products are in demand with the population, such as warm fabrics and garments, knitted goods, fuel, and so on. What steps were taken to ensure proper supplies of these commodities?

[Answer] In the textile-footwear sector we ensure supplies of a larger amount of season items to the stores. Compared with the same period of last year, in this quarter we are marketing 8.5 percent more overcoats for adults and children, 6.2 percent more knitted goods, 5.9 percent more footwear out of substitutes, man-made material and rubber, and greater quantities of warm fabrics (twilled cotton, flannelette, and velveteen). Moreover, we ensure supplies which are 5 percent greater for heaters that use solid fuel, 6-8 percent greater for housewares for the cold season, and so on. Furthermore, we continue to ensure the supplies of firewood and coal for the winter, in the amounts needed for sensible consumption; in case of adverse weather, season warehouses will be opened.

For the full implementation of the provisions in the marketing plan for the fourth quarter, just as of the provisions for the entire winter period, the supplier units must strictly meet their contractual obligations and take steps to eliminate the backlogs in terms of some specific cold season items.

[Question] What are the provisions for 1981?

[Answer] According to the Uniform National Plan for Socioeconomic Development of Romania in 1981, the total volume of retail sales of goods through the socialist trade units will be 225.5 billion lei, with a significant increase over the level for 1980.

In light of the instructions given by party secretary general Nicolae Ceausescu, for next year the product structure of commodities was determined according to classes of quality: lower-priced products, representing 50 percent of the total of consumer goods, which are specifically meant for people with lower incomes, and some products of higher quality. Based on this new orientation of the production and marketing of consumer goods, we ensure the firm application of the principles of socialist ethics and equity and also create greater facilities so that the population may find, according to their incomes, products conforming to their needs.

Also, an important factor will involve the increased input of counties in establishing the fund of goods, by achieving a supplemental output, as a result of purchasing extra amounts of produce from the available resources of the population and by expanding small-scale industry. For the purpose of assuring balanced supplies throughout the country's territory, the 1981 plan assignments were determined for the various counties -- in addition to the total volume -- also in terms of a number of important products.

[Question] Please give us a few details on contracting for the fund of commodities for 1981.

[Answer] From the outset I would like to point out that special attention was paid to the projects of contracting for the fund of commodities for next year, based on the broad consultation of the county councils of consumers' representatives conducted at the 11th Consumer Goods Fair. The better substantiation of the needs for goods of trade units was achieved through the various forms of surveying the needs of the population, which involves a new and vigorous manifestation of the democratic nature of our socioeconomic life.

In light of the specific character of each group of commodities, the nature of production and of consumption, the procedures of contracting for the fund of commodities for 1981 developed in phases for nonfoods. For farm foodstuffs, contracts will soon be finalized, at the conclusion of agricultural balances. In the textile-footwear sector, contracts were concluded, valued at more than 20 billion lei. They mostly involve -- in accordance with the specific nature of these items -- the merchandise which will be delivered to trade units in the first half of next year. I must point out that -- from the displays at the fair -- contracts were concluded for about 5500 styles of garments, knitwear, footwear, notions and leather items, and other goods, largely new and modernized products.

In the metalochemical sector, firm contracts with industry involved commodities totally valued at 28.3 billion lei, with more contracts in the process of being concluded, designed to fully cover the fund of commodities planned for next year. For instance, in the furniture sector, contracts involve a

fund of commodities valued at more than 800 million lei, in a range of products that was renewed 35 percent. Moreover, the contracts concluded for 1981 -- in comparison to 1980 -- will result in significant increases for the products in higher demand on the market, such as: 18 percent for detergents, 15 percent for compressor refrigerators, 10 percent for earthenware tiles and bathroom items out of earthenware, 12 percent for bathroom fixtures, 10 percent for electrical batteries, 15 percent for tires, and other items, for the purpose of better meeting the needs of the population for these goods.

While by and large, adequate quantities were ensured under contracts for most products, there still are some commodities for which the manufacturing enterprises are required to make supplementations. These must be made as part of the 10 billion lei supplementation for next year established by the party and state leadership. This actually also is a central concern of ours, the workers in the area of trade, namely fully ensuring the fund of commodities envisioned under the plan and its smooth transfer from the furnishing units, for the purpose of the proper supply of stores.

[Question] However, there are cases when some kinds of merchandise are harder to find in the stores. Why?

[Answer] There are complex causes. One of them involves unsmooth delivery of some products, a fact that creates temporary hiatuses in supplying the stores. Of course, in conjunction with industry, we try to avoid these situations and make efforts to assure continuity in supplying the entire trade network.

In other cases, the situations which you mentioned result from some deficiencies in the transfer of goods from warehouses to the trade units and from the dishonesty of some trade workers who -- instead of putting up for sale the entire range of merchandise received -- promote sales of some products only to special buyers, in exchange for material benefits. It is an attitude which we totally disapprove, because it contradicts the principles of socialist ethics and equity. We take firm action against these attitudes, by various educational procedures and, when appropriate, by disciplinary measures.

For the purpose of providing civilized, correct and prompt service to shoppers, as part of recent projects, conferences were held in some towns in the provinces and in Bucharest -- organized in conjunction with the Union of Trade and Cooperative Trade Unions -- with the executives and active of local trade. These conferences were geared to highlight the good results obtained in this field and also to discuss violations of trade regulations and laws of our state by some workers and to take appropriate measures.

Under the guidance of party organizations, the efforts to educate trade workers in the spirit of socialist ethics and equity and the country's laws will be stepped up.

In this program to eliminate negative phenomena from trade, citizens ought to more firmly speak out and protest against the buyers who purchase quantities

that far exceed their needs and thereby prevent other buyers from satisfying their needs. The Ministry of Domestic Trade, through its central and territorial apparatus, has taken -- and will continue to take -- measures of severe punishment, going as far as removing from the trade sector the workers who promote such actions. However, it is the duty of all shoppers to take immediate action whenever buyers show tendencies toward excessive purchasing.

By acting on this line at all levels in the trade sector, in close cooperation with the consumer goods industry, by most intelligently using the existing trade network and completing new trade facilities -- the minister concluded -- the trade sector will better implement its highly responsible tasks in the area of providing supplies and serving the population.

SUCCESSES, REQUIREMENTS IN STANDARDIZATION OF PRODUCTION

Bucharest ERA SOCIALISTA in Romanian No 22, 20 Nov 80 pp 8-10

/Article by Dr Eng Ion Hera-Bucur/

/Text/ As we know, more than a year ago at the Working Conference with Technological and Construction Designers Comrade Nicolae Ceausescu outlined a new plan for the content and organization of typification activity in Romania that will make it an effective instrument for rationalizing production, reducing material inputs and improving product quality and reliability. As Comrade Nicolae Ceausescu said at the Plenum of the RCP Central Committee of 14-15 October 1980, "Steps must be taken to finish up operations for typification and setting material consumption norms more rapidly, because the 1981 plan and the five-year plan are based upon rational norms, rational inputs, and typification of the products, materials, and various assemblies and subassemblies, and that means we must provide for the proper technical level, quality and productivity."

A Source of Great Savings

In its general sense typification means the activity of developing technological, organizational, structural and other measures accepted as best suited technically and economically to the given purpose and the respective stage and specifying them in the technical documentation. The scope of typification in the Romanian economy is so broad that it can be said without exaggeration that industrial progress is now impossible without development of this activity and large-scale application of the technical norms and standards for sectors, consumption norms and other regulatory documents resulting from the process of typification and standardization.

Typification is one of the activities that have received the necessary recognition and full support of Romania's leading authorities. This encouraging statement is made by all specialists in plants, research laboratories or technological engineering and design sections, who are aware of the powere of typification and standardization for socioeconomic change and have devoted much labor over the years to promoting the theory and practice of this applied discipline.

In the last period Romanian typification and standardization were urgently confronted with the dilemma of diversification-specialization, in view of the necessity of meeting all demands of the domestic and foreign markets with economical manufacture

and a greater contribution on the part of typification to conservation of materials, energy and fuels.

The effort to typify construction operations was intended, in the first place, to restrict the number of procedures that are designed, which often contain duplications, on the basis of a detailed analysis of the entire supply of designs, and in the second place to extend the scope of typification to new fields of construction because standard designs had not been prepared in the past or existing designs covered too limited a field to meet the needs of the economy. Study of over 1,500 construction designs in 1979-1980 and correlation of the most technically and economically successful solutions resulted in about 700 standard designs (more than 50 percent less) that are now in use, including 144 models and standard designs for capacities common to several sectors such as water tanks and sedimentation tanks, boiler rooms for steam-generating stations and heating stations burning solid fuel for heating housing subassemblies, cooling towers (with forced or natural draft), water supply and sewerage projects etc. The preliminary estimates indicate that application of the standard designs will save nearly 600,000 tons of cement in the next five-year plan, about 130,000 tons of steel, over 600,000 tons of conventional fuel and almost 5 billion lei in construction-installation operations compared with the procedures in use before typification.

Outstanding results were obtained when typification was based on interdisciplinary and multidisciplinary studies such, for example, as corroboration of the studies made in construction and the construction materials industry for designs of light structures of allied materials and extended use of precompressed concrete, economical profiles of sheet steel etc. Wide-scale application of new structural systems has been recommended, with simplified joining and intensive industrialization of the designs, with spaces and compartments limited to dimensions strictly necessary for the industrial functions of the buildings. Further use is being made of local materials and and by-products as, for example, ash slag from heat and electric power stations, phosphoric gypsum, gypsum plaques and strips, and fiberboard. To rationalize use of fuels and to reduce energy consumption, effective measures (triple windows, double skylights) have been recommended to improve thermal insulation of buildings, as well as use of less energy-intensive materials, rationalized systems of heating installations, recovery of heat, use of solar energy, etc.

The foregoing data bear out the correctness of employing major planning and development forces in enterprises and institutes to prepare studies, designs and other technical-regulatory documents for typification in construction, and especially the necessity and advantages of continuing typification work in this production sector on a higher level in the next period. The main improvement in typification in this sector consists of integrated examination of manufacturing methods, industrial equipment and the structural design of the buildings, as opposed to the methods previously in use when typification was confined solely to construction properly speaking.

Application of the methods of typification and standardization to design of machines, equipment, assemblies and industrial installations provides great possibilities for rationalizing production. The number of more than 700,000 standard sizes of products in manufacture in metallurgy, machine building, chemistry, construction materials, light industry etc. can be reduced by about 50 percent, with expected savings of almost 1.1 billion lei in 1980 and over 5.1 billion lei in the next five-year plan. The savings will be made by simplifying production and lowering its costs, introducing new industrial processes, using more efficient producer goods, reducing costs of preparing manufacture per unit of output, etc.

Upon examing the methods of typification used in various economic sectors, we shall note that in metallurgy, for example, the emphasis was on output of a limited range of standard sizes of iron and steel products to meet a wide range of requirements. By improving the quality of the metal and intensifying studies of the beneficiaries' real needs, the number of standard varieties of ferrous products was reduced from about 180,000 to nearly 90,000, and that of makes of steel from 700 to 166. Henceforth ferrous metallurgy will produce strictly necessary varieties and standard sizes, according to the lists, standards and other technical-regulatory documents prepared and approved at the start of this year. This will permit reduction of the number of methods of steel processing and greater production capacities through more rational use of metallurgical machine tools and a constant product quality. Estimated savings in the metallurgical sector thanks to the recent typification program are expected to exceed 140 million lei by the end of 1980 and to reach about 600 million lei for the next five-year plan.

Typification of the products of the machine building sector required analysis of more than 300,000 standard sizes of machines and equipment, resulting in suggestions to stop manufacture of about 42 percent of the standard sizes and varieties, which suggestions will lead to expected savings of almost 800 million lei in 1980 and over 3 billion lei in the course of the 1981-1985 plan. Efforts were made to reduce the number of obsolete products with outmoded structural and functional parameters or those with different structural characteristics although they were intended for the smae manufacturing process. The effort was also made to manufacture in Romania as many products as possible that are now imported, as well as some very common materials and supplementary subassemblies. One important result of the typification operations in machine building was the final determination of the basic structures of the systems of machines and equipment for the main types of manufacturing processes. This will make it possible to rationalize their design and manufacture and, ultimately, to completely mechanize the production sections and buildings.

Comparable results were also obtained in the other economic sectors, such as light industry, the forestry and construction materials industry, transportation, the enterprises of the Ministry of Electric Power, the mines, petroleum and geology sectors etc., where typification activity has recently acquired qualitatively new dimensions and aspects compared with what had been previously initiated and accomplished in this field.

All these sectors as well as the ones mentioned above still have great potentials for expanded typification and its greater effectiveness in the future. For example, typification must be intensified in road construction and cement consumption must be reduced through wide-scale use of slag and ashes from heat and electric power stations, traditional local materials etc. Development of standard designs for small electric power stations and hydroelectric power stations to exploit the entire energy potential of Romania's inland rivers shows great promise. In agriculture, it is rational to continue making low-capacity units according to the needs of each county, and light industry has great potentials for making many construction materials to replace the scarce and expensive ones. This applies especially to the light and cheap materials used in manufacturing some construction elements, those needed for high-quality thermal insulation, etc. In the construction materials sector it is possible to assimilate a larger assortment of materials, sections and simple space elements, to introduce domestic materials into the production cycle, to make better use of the natural resources in each geographic area, etc. And

finally, efforts must be made everywhere to reduce the inputs of energy-intensive materials and to use more cheap local materials.

Requirements for Better Activity

Analysis of the experience acquired in typification of constructions and industrial products in Romania in the past year especially brings out the great possibilities of this activity, which are far from exhausted, for a more active contribution to rationalization of production and its greater economic effectiveness. In the construction sector, for example, this possibility lies in better correlation of typification operations with setting scientific norms for the material inputs, so that any standard design will be accompanied by lists specifying ceilings on the quantities of materials (cement, metal, wood etc.) neededfor the respective construction, just as the standard prices are set in the general estimate of any new investment capacity. In this way typification can become an efficient instrument for applying the new economic-financial mechanism based on growth of net physical production or of the newly created value in the production process along with reduction of material inputs. In connection with the above-mentioned point, specially formed collectives must prepare the designs for typification of all construction materials, wherein special emphasis is required on development of production of the materials which call for limited inputs of fuel and energy and which are plentiful in Romania.

Since in most cases the machine building industry has emphasized typification of the finished products more than unification of the structural components of the various types of products with the same structural and functional characteristics, it would be desirable to shift the emphasis in typification there henceforth to the latter consideration. Intensified typification and unification of the structural elements of the products (assemblies, subassemblies and parts) will accomplish the present most important objective of Romanian typification, namely the greatest possible diversification of the products along with the greatest possible reduction of the number of their components. As a matter of fact, advanced experience in the field of typification indicates that any new product or any variant of an existing product must be manufactured with 90-95 percent typified elements and no more than 5-10 percent particular, original elements. This increases the series manufacture of the parts and subassemblies and guarantees application of advanced working methods as well as minimal losses of materials and energy inputs. Party Secretary General Nicolae Ceausescu stressed this point on his visit of 26 June 1980 to the Bucharest Machine Tool and Aggregates Enterprise, when he requested "measures to be taken for more rapid transition to the program for typification of subassemblies and to manufacture of production lines and machine tools on that basis." But the comment applies to most of the subsectors of the machine building industry and not just to the machine tools group, where this shortcoming was found.

Great possibilities for more effective typification, so far insufficiently exploited, are offered by better combination of that activity with the measures and principles of specialization and cooperation. In this respect there is no technical or economic justification for situations where production of the same group or family of equipment (for example, machines and equipment for metal processing by hot or cold plastic deformation) is fragmented from the standpoints of research, design, assimilation and manufacture among several planning and development institutes, enterprises and industrial centrals. Similar cases are also encountered in the case of other groups of machines. A problem that has been underemphasized so far and one which I think should receive more theoretical and practical consideration henceforth

is that of typification of manufacturing methods, as a natural corollary of typification of the products in machine building and other fields. And finally, it is vitally necessary to promote rationalizing calculations in typification-standardization activity, based upon use of objective criteria indicating how far unification and restriction of types of makes and products do not affect the output of the sectors that are beneficiaries of the standard varieties demanded by the technological requirements and those of economic effectiveness.

Of course maximum economic effectiveness is the final criterion for justifying any typification operation, since the output produced with typified equipment and materials will be reflected in the lowest possible production and especially material outlays in all the economic and other sectors that use the typified product. This calls for complete quantification of economic effectiveness throughout the production-exploitation (consumption) cycle and not in one area of it alone. Generalization of the measures based on rationalization and of the calculation of the integrated economic effectiveness are qualitative considerations that should govern typification, as well as major requirements with which practice confronts typification and standardization in the present stage of development of the Romanian economy.

It is becoming increasingly clear that the new forms of typification and standardization advanced in recent years by modern science and technology must be promoted, such as systemic treatment of typification, overall standardization, and preliminary standardization. In considering in depth the last concept alone, that of preliminary standardization, we note that under the conditions of accelerated technical-scientific progress the technical-economic indicators adopted in the planning stage of a product often cease to be competitive in the course of assimilation and reaching the stage of industrial production, even if it was originally based on the latest studies and advances in science and technology. Therefore when the products are designed the specified indicators must be calculated to guarantee that they will be viable in time. To this end typification and standardization must be oriented not only toward regulation of the existing output but especially toward the products in the designing stage or even in that of ideas and development, where technical and economic forecasting calculations are used.

From the standpoint of coordinating typification operations, the collectives in enterprises and institutes that are responsible for that activity feel the effects of inadequate methodological training and guidance, as indicated especially by the absence of any uniform or clear subject matter or conception of the work. As a result differing viewpoints have often been adopted, operations have been repeated several times, important subjects of typification have been undertaken very late (imports for example), etc. Such defects can be eliminated in the future by more attention to the theoretical and methodological aspects and guidance of typification and by closer collaboration among the elements with such responsibilities on various levels. These points were discussed at the National Symposium on Typification in Machine Building held between 3 and 5 July under the auspices of the Ministry of the Machine Building Industry and Brasov University, where the necessity of developing the science of typification and standardization was urgent on the agenda.

The standard and effectiveness of typification can be greatly improved in the light of the older and newer experience acquired in Romania and on the basis of more regular information concerning progress in other countries. This objective calls for persevering efforts on the part of highly qualified specialists who also have sufficient flexibility of thought and action. The training of such specialists clearly

begins in college, and then the first years after graduation are critical. For the foregoing reasons, we note with satisfaction the recent regulations on direct assignment of well-trained and gifted graduates to research and design. It now depends upon good organization and management of the new graduates' apprenticeship on the part of those who work in the research and design sections to which they were assigned, so that while mastering the technological innovations in the field they will enhance their skills acquired in college at learning thoroughly and permanently. Experience shows that the youths in this category are highly receptive to design procedures based on the principles and methods of typification and unification, something that does not always come easily to engineers in the older classes who have practiced designing by classical, traditional methods all their lives.

LAW REGULATES DEVELOPMENT OF SMALL INDUSTRY

Bucharest BULETINUL OFICIAL in Romanian Part I No 89, 22 Oct 80 pp 1-7

[Law Regarding the Development of Small Industry]

[Text] On the basis of article 57 of the Romanian Constitution, we sign and order to be published in BULETINUL OFICIAL of Romania, Law No 2 of 17 October 1980, regarding the development of small industry.

Nicolae Ceausescu
Chairman of the Socialist Republic of Romania
Bucharest, 21 October 1980

Law Regarding the Development of Small Industry

The fulfillment of the program for building a multilaterally developed socialist society imposes the most efficient use of all material resources and of the labor force available in the national economy, and a sustained increase in the value derived from them.

In this context, an important role is played by the material and labor resources existing in communes and towns, which can be utilized in small industry.

Small industry conducts its activity under the direct leadership and guidance of peoples' councils; its major goal is to contribute to the development of material production in society, mainly through the exploitation of natural resources, secondary animal, vegetal, and industrial products, reusable materials, as well as other resources of raw materials and local materials.

Similarly, small industry must seek development and diversification in the production of consumer goods and services, so as to properly satisfy the demand of the population and other needs of the national economy. A special role in these activities must be played by the production of craft and folk art items, so as to substantially increase the proportion of small industry products for exportation.

Small industry must help create conditions for including in production and service activities, the available labor force throughout the year, assuring for those who work in this domain, incomes that correspond to their production.

For this purpose, the Grand National Assembly of Romania adopts the present law.

Chapter I. General Provisions

Article 1. Small industry, an integral part of the socialist economy, constitutes an important domain of the society's material production which must make an increasingly large contribution to the general development of the economy and the continued improvement of the population's standard of living.

Small industry includes the production and service units of peoples' councils, crafts cooperatives, consumer cooperatives, the industrial activities of agricultural production cooperatives, as well as the activity of authorized small craftsmen and other production and service activities organized according to law.

The principal objective of small industry is the production of consumer goods, household and housekeeping articles, toys, textiles and clothing, folk clothing, rugs, other craft and folk art items, food products, construction materials, fabrication, repair, and reconditioning of parts, assemblies, and subassemblies for the needs of the population and industry, housing maintenance and repair, production of goods in cooperation with other economic units, milling, and other services, so as to satisfy the demands of workers and socialist units, as well as exportation needs.

Article 2. All small industry activity is carried out under the guidance and coordination of peoples' councils, independently of the affiliation of the units in which it is conducted. Peoples' councils are responsible for the good organization of activities in production and service units, the efficient utilization of material resources and the labor force, and the most satisfactory fulfillment of the population's demand for products and services.

Article 3. Small industry units operate according to the principles of worker self-management and economic-financial self-administration, on the basis of their own income and expense budgets, assuring a sustained growth in income and the most efficient utilization of all their material and financial means.

In keeping with the economic-financial mechanism, small industry units must achieve a high economic efficiency through a superior utilization of raw materials, and the production of inexpensive items with the highest possible degree of processing and value, low production costs, and corresponding profits, according to law.

Small industry must assure increased production and services, so that each unit will contribute to the general development of society, and form its own funds for self-financing and for covering other expenses stipulated by law.

At the same time, the activity of small industry must assure a judicious stewardship of goods, the exercise of rigorous control, as well as heightened responsibility, order, and discipline in the labor process.

Article 4. Small industry must contribute to the exploitation of all material and labor resources available in communes and towns, and to increased production of goods and services through the introduction into the economic traffic, of all available raw materials and local materials, assuring primarily:

a) The production development of some construction materials through the extraction and processing of quarry and river gravel, sand, marble deposits, calcareous rock, volcanic tuff, clay, and other similar materials;

b) The organization of extraction and exploitation from small deposits and deposits with reduced reserves, of coal, peat, iron, copper, gold, and silver ores, as well as other low-grade metallic and non-metallic resources for the steel, metallurgical, and chemical industries, and of semi-precious and similar stones;

c) The most extensive possible use of cane, straw, sorghum, corn leaves, cattails, reeds, sedge, and other similar local raw materials, so as to produce items for domestic consumption and exportation, as well as a substantial expansion in the exploitation of medicinal plants, and of vegetal and mineral raw materials to obtain chemical products, paints, cosmetics, and so on;

d) The production development of canned, semi-preserved, and other food items derived from the processing of available agricultural products, secondary vegetal and animal products, mushrooms, forest harvest, and other similar raw and other materials;

e) The organization of the exploitation of wood resulting from windfalls and forest clearings, in inaccessible locations, with the approval of the Ministry of the Forestry Economy and Construction Materials, and the use of these materials to produce consumer, craft, and other goods;

f) The production development of tool kits and small tools, highly processed, small scale sports and travel goods, small and complex machine tools for technical, radio, physics, and chemistry applications, small-run products for teaching, and so on.

Small industry will also assure the collection and utilization, as a function of plan tasks, of raw materials and reusable materials, parts and subassemblies obtained from the dismantling of used fixed assets, durable, and personal goods, metal resources, chemical products, wood materials, textiles, leather, residual agroalimentary substances resulting from production and consumption processes, and so on.

Article 5. The development of small industry activity will be oriented so as to bring industrial production and services closer to the population, through the creation of a broad and diversified network of small, readily accessible units, which will provide varied, prompt, and high quality services, thus eliminating unnecessary transportation and displacements.

Article 6. The development of small industry activity will primarily use the space, machinery, tools, and devices available in their respective units of in other units of the economy, through redistribution, transfer, or rental under prevailing regulations, as well as through cooperative actions.

Article 7. The activity of small industry must be carried out with reduced energy consumption, making the largest possible use of secondary resources and lower grade fuels.

In order to satisfy their own power needs and those of socialist units and the population, small industry units will build micro-hydroelectric plants, installations for using solar and wind power, water power (mills, sawmills, carding stations, and so on), as well as biogas plants, and if need be, only some parts or portions of such plants and installations.

Article 8. The products fabricated by small industry are sold on the basis of contracts with socialist organizations, for domestic and foreign use, as well as directly to the population. In addition, some products can be sold through sales units of small industry at fairs, markets, and so on, according to prevailing regulations.

Article 9. Small industry units will make it possible to make use of the available labor force for the production of material goods and for services; cottage industry production and services will be expanded and diversified by employing women, retirees, the handicapped, and other similar categories of people.

All workers who are active in small industry will derive incomes on the basis of agreements, piece rates, or percentages, in direct ratio to the volume of their production or effective services.

Chapter II. Organization of Small Industry Activities

Section I. Organization of Activities in Peoples' Councils Units

Article 10. Municipal, town, and communal peoples' councils organize in accordance with prevailing legal provisions, small industry units within their own territorial-administrative areas, to produce material goods and services to satisfy the needs of the population, socialist units, and exportation. Some units can be organized according to law, subordinated to county peoples' councils.

Similarly, peoples' councils together with educational organs will develop small industry activities carried out as production practice for school, high school, as well as higher education students, so as to fabricate industrial products, and especially consumer goods.

Article 11. Units organized by peoples' councils will primarily assure the production of construction materials, household and housekeeping items, food products, and other consumer goods for satisfying the needs of the area's population; they will produce and restore parts, devices, and subassemblies in cooperation with units of the national industry and other socialist units; manufacture products and conduct projects required by units of local state organs; and render services, including milling, chemical cleaning and washing, housing maintenance and repair, and other activities for citizens and socialist units.

Article 12. Units subordinated to peoples' councils are established and organized according to legal provisions.

Article 13. The activity of peoples' councils units will consistenly seek to apply the principles of worker self-management and economic-financial self-administration, to develop production and increase economic efficiency, and to increase their contribution to local budget incomes.

Article 14. Peoples' councils will assure the development of the raw and other material basis necessary to the economic activities of the units which they organize, the collaboration and cooperation of these units with state or cooperative units, and will attract, train, and use the available work force in these activities.

Section II. Organization of Activities in Units of Crafts Cooperatives, Consumer Cooperatives, and Agricultural Production Cooperatives

Article 15. Small industry units are organized by crafts, consumer, and agricultural production cooperatives in accordance with legal regulations regarding cooperative activities, statutes of cooperative organizations, legal regulations regarding the development of economic and service activities in cooperative units, as well as other legal provisions.

Article 16. The activity of small industry units of cooperative organizations is conducted on the principles of worker self-management, economic-financial self-administration, and cooperative democracy, by drawing all cooperative members into the management of public affairs at general assemblies and within other management organs stipulated by statutes.

Article 17. Small industry units of crafts cooperatives are organized and conduct their activities primarily in urban areas. The major objectives of these units is to provide services to the population and socialist units; produce consumer goods, as well as folk art and craft items; and fabricate and repair parts, devices, and subassemblies by cooperating with state industrial enterprises and other socialist units, for domestic consumption and exportation.

Organizations of crafts cooperatives will develop the purchase, reconditioning, and resale of durable goods from the population, as well as the repair and reconditioning of assemblies, subassemblies, and other spare parts for their own needs and those of other socialist units.

Article 18. Production units of consumer cooperatives are organized primarily in rural areas. Their major objectives are to produce consumer goods, household and housekeeping items, crafts, bakery goods, preserves and semi-preserves of vegetables and fruits purchased from the population, and other food products; provide services of an industrial nature to the population and to socialist units; and produce and recondition parts, devices, subassemblies, and other goods, including through cooperation with industrial enterprises and other socialist units, both for the population and for exportation.

In addition, as part of their services in non-cooperative rural localities, consumer cooperative units can form specialized teams for housing construction, organize the transportation of goods using animal traction, and provide services of a non-industrial nature to the population.

Article 19. The major objectives of small industry in agricultural cooperative units are to process and industrialize agricultural products; extract, process, and sell minerals and wood; produce construction materials, consumer goods, and crafts from vegetal raw materials and other materials specific to the forestry and

agricultural sectors; fabricate and recondition parts, devices, subassemblies, and other goods, including through cooperation with industrial enterprises and other socialist units, for domestic consumption and exportation; and provide services to the population and socialist units, especially in rural areas.

In addition, as part of their service activities, agricultural production cooperatives can form specialized teams for housing construction in rural areas, and can organize the transportation of goods for the population's needs, using animal traction.

In organizing and developing the activities stipulated in paragraphs 1 and 2, the managements of agricultural cooperative units and county agricultural organs will seek consistently to increase their contribution to the economic consolidation of each unit; satisfy as fully as possible the specific needs of commune inhabitants, other needs of the economy, and exportation; better exploit the resources available in each unit; and assure that the labor force of peasants in cooperatives is fully and reliably employed throughout the year, and that the income of this labor force is increased.

Members of agricultural production cooperatives can usually work in small industry activities within the cooperative organizations to which they belong.

Activities are organized in agricultural production cooperatives and inter-cooperative economic associations of an agricultural nature -- as separate economic sectors with their own income and expense plans -- as well as in inter-cooperative economic associations of an industrial nature.

Article 20. In order to satisfy as well as possible the population's need for services in rural areas, agricultural mechanization stations will organize in their own mechanization departments and shops, activities for maintaining and repairing agricultural machinery, other mechanical, electrical, and automotive equipment, as well as radios, television sets, and other household and housekeeping items.

Article 21. All cooperative units must organize small industry activities according to economic and high efficiency criteria, fully cover their expenses from their incomes, as well as obtain and distribute profits in accordance with legal provisions and statutes.

Article 22. Those who are active in small industry units organized by cooperative units, can participate with monetary means in the development funds of the units to which they belong, and are entitled to receive from the profits of the units, annual incomes proportional to the sums contributed by them.

The rates for contributions and the rights created by these contributions are those regulated by law and by the statutes of crafts cooperative, consumer cooperative, and agricultural production cooperative organizations.

Section III. Activity of Small Craftsmen

Article 23. In order to most fully meet the population's demand for some services, products, and projects, small industry activities can also be conducted by small craftsmen authorized according to law.

The activity of small craftsmen is carried out in close association with crafts cooperatives, which support the development of their products and services, supply them with materials, tools, equipment, and so on, guide the proper performance of their services to the population, organize their inclusion -- according to law -- into the social security system of crafts cooperatives, and improve their working and living conditions.

In rural areas, the production of small craftsmen is recorded and reported through consumer cooperative organizations, and in urban areas through crafts cooperative organizations.

Article 24. Authorization to exercise a trade can also be issued to some retirees who reach the age at which units can request retirement according to law. In this case, the respective retirees are entitled to cumulate their full pension with the monetary income derived from their work.

In their activities, small craftsmen can be assisted by their families, and can train 1-3 apprentices in their shops according to prevailing regulations.

Article 25. Depending on the specific trade and size of shop, a number of 1-3 persons may work in small craftsmen's shops after finishing their apprenticeships. The pay rate for these workers is established on the basis of elements of the remuneration system that is used in crafts cooperatives for similar work.

Article 26. Small craftsmen are supplied with raw materials, materials, parts, accessories, tools, and so on, from local resources, as well as from units of the state and cooperative commerce that operate in similar specialties, according to prevailing regulations. To this end, small craftsmen will be supported through the distribution of reusable materials from state and cooperative units.

State and cooperative socialist units can conclude contracts with small craftsmen for the fabrication of parts, devices, and other products. In this case, the necessary materials can be provided by the customer unit, and payment is based on piece work rates.

Article 27. Authorized small craftsmen can associate with one another to fabricate products or execute projects, on the basis of contracts concluded with state or cooperative units, or with the population.

The incomes derived will be taxed individually for each associated craftsman.

Article 28. Small craftsmen must declare to financial organizations the incomes which they receive, and must pay the taxes established by law.

Small craftsmen are entitled to pensions and other social security rights as part of the crafts cooperative system.

Section IV. Other Activities

Article 29. Peoples' councils, other state organs, and cooperative organizations can turn over to physical persons, for administration and management, production and services units with a small volume of activities and with 1-3 workers, on a contract basis under conditions stipulated by law.

The money due to persons who have contracted for the administration and management of units, is prorated from net incomes, representing the difference between gross incomes and expenses, according to law.

Article 30. In order to exploit alluvial reserves of minerals, precious metals, and semi-precious stones, or those in zones that are not industrially exploitable, the appropriate state organs can authorize physical persons, including retirees, to extract these minerals together with their families.

The conditions for conducting the activities stipulated in paragraph 1, as well as the rights and obligations of the persons authorized to perform these activities, are those determined by law.

CHAPTER III. Joint and Final Provisions

Section I. Provisions of an Economic and Financial Nature

Article 31. The activity of small industry will be included in the unified national plan for socioeconomic development. Under conditions stipulated by law, some of the materials necessary for this activity will be provided from the state fund.

Article 32. In order to develop small industry activities, state and cooperative units will initiate and organize cooperation and association actions according to law.

For this purpose, ministries, other central organs, and peoples' councils will assist in providing the necessary space and equipment, and will organize and develop economic cooperation actions, so that the use of development funds for such activities will be as restricted as possible.

Article 33. In small industry units, remuneration is determined by the effective production or services provided, on the basis of agreement or piece rates, or of tariffs or percentages for services rendered, corresponding to the branch or sub-branch of the respective unit, as well as on the basis of receipt percentages. The incomes of small craftsmen and those obtained on the basis of receipt percentages will be taxed according to legal provisions.

Retirees who work in small industry activities organized according to the provisions of the present law, are entitled to cumulate their entire pension with the incomes obtained through these activities, with payment of the taxes stipulated by law.

Article 34. In small industry units, those responsible for the units, or the leaders of work teams, receive and issue customer orders, receive payment for products and services, maintain records, and conduct other such activities, while participating directly in production.

In small industry units, the persons who also fulfill the function of responsible party can receive in addition to their due for their own achievements, as much as 30 percent of the incomes obtained by all the workers in the unit, but no more than 25 percent of their own rate of remuneration.

Article 35. The determination of prices, rates, profits, and taxes, the constitution of funds, the granting of bank credits, as well as other financial and economic aspects of small industry activities, are subject to prevailing legal regulations.

Section II. Use of Work in the Home

Article 36. Small industry units of peoples' councils, crafts cooperatives, consumer cooperatives, and agricultural production cooperatives, can also use work in the home for their production activities, based on analyses and economic calculations which show that this form of production organization is adequately efficient.

The list of products, projects, and services which can be performed in the home is established by central organs and executive committees of county and the Bucharest peoples' councils for their subordinated units.

Article 37. Work in the home will be performed as follows:

a) Based on a civil agreement for the fabrication of products or performance of projects at home, with rights only to remuneration for activities performed. This agreement is made when the performance period for products or projects is of up to three months, or when the assured production volume does not justify a labor contract;

b) Based on a labor contract for performance of work in the home. This contract is written for a predetermined period for productions which require an uninterrupted activity of 3-12 months, or for an undetermined duration for productions which require an uninterrupted activity of more than 12 months.

The agreements and contracts stipulated in paragraphs a) and b) cannot be made with persons already employed in the labor force.

Those who make agreements or labor contracts for work in the home cannot use salaried persons to perform these activities.

Article 38. Contracts and agreements for work in the home will stipulate the conditions for raw and other materials supplies, the conditions for receipt and delivery of products, and rates for the work performed.

Article 39. The rights conferred by the status of person employed in the labor force, to which are entitled those who work in the home on the basis of a work contract written under the conditions of article 37, letter b), are granted if the person delivers a production volume equal to the one established for those employed and active at a unit's work site, according to standards established by the Ministry of Labor, with the approval of the General Union of Trade Unions.

Article 40. The provisions of article 86 of the Labor Code, regarding the remuneration of persons employed in the labor force in the case of production interruptions for technical or other reasons, do not apply to persons working on the base of work contracts for work in the home.

Article 41. The remuneration for persons who work in the home is established by agreement, depending on the work rates and tariffs used by the customer enterprise, corresponding to the remuneration level assigned to those persons, within the fund limits approved for this purpose, and according to law.

Article 42. Socialist units which organize work in the home must create and maintain current work and accounting records that will assure a rigorous control of work in the home activities. For this purpose, those who work in the home will receive from their unit "individual production and remuneration books," standardized for specific activities by prevailing legal regulations.

Article 43. Those who work in the home carry a material, civil, administrative, disciplinary, and penal responsibility -- as the case may be -- for the proper stewardship of the raw and other materials entrusted to them by units, as well as for their utilization in accordance with established technologies and for the exclusive performance of the work contract or agreement.

Depending on the value of the raw and other materials that are entrusted, contracts or agreements with those who work in the home will provide for material or personal guarantees from other workers employed in the labor force, under conditions stipulated by law for administrators.

Article 44. Under the current law, work in the home can also be used by units subordinated to ministries and other central organs.

Article 45. The Committee for Peoples' Councils Problems, ministries, and other central organs which are responsible for units that use work in the home, will formulate with the approval of the State Planning Committee and the Ministry of Labor, technical specifications of a methodologic nature regarding the organization of work in the home.

Section III. Coordination, Guidance, and Control of Activities

Article 46. The committees and executive bureaus of peoples' councils are responsible for guiding and controlling all small industry activities organized within their territorial administrative areas. To this end, they have the obligation of periodically examining the manner in which small industry units conduct their activities, and of assuring the satisfaction of the needs of the population and other customers, as well as the need to expand and diversify existing activities.

At the same time, through the county and Bucharest commissions for coordinating the production of consumer goods, and through councils for coordinating and guiding supply and service activities to the population, the committees and executive bureaus of peoples' councils will assure the orientation and coordinated development of these activities in each territory.

Article 47. The Committee for Peoples' Councils Problems, the Ministry of Agriculture and the Food Industry, the Central Union of Crafts Cooperatives, the Central Union of Consumer Cooperatives, and the National Union of Agricultural Production Cooperatives, will assure the guidance and support of peoples' councils and cooperative organizations, for the development and diversification of small industry production, under the conditions stipulated in the present law.

The collective management organs of cooperative organizations must take steps to develop and diversify production and services and assure their good quality, so as to satisfy under the best conditions the demands of the population and to increase contributions for exportation.

Article 48. The State Planning Committee will assure that all the production potential of small industry units is included in the draft of the unified national plan for socioeconomic development, so as to increase their contribution to production development in order to satisfy the demands of the population, of other needs of the economy, and for exportation.

Similarly, together with peoples' councils and other plan assignees, the State Planning Committee is responsible for the execution of the small industry plan, exercises sustained control over the fulfillment of assigned tasks, and initiates or adopts measures for the balanced and efficient development of small industry units, as well as the superior utilization of all material and labor resources.

The Ministry of Technical-Material Supply and Control of the Management of Fixed Assets, together with peoples' councils and other plan assignees, is responsible for proper supplies to small industry and for the collection and utilization, in accordance with plan tasks, of reusable materials and other local resources, and assures rigorous compliance with legal provisions regarding the formation and use of these resources.

The Ministry of Finances guides and controls the entire economic-financial activity of small industry units, assures compliance with legal provisions in the formulation and execution of income and expense budgets, and adopts or proposes measures to increase economic efficiency, responsibility in the management and use of funds, and plan and financing discipline.

Article 49. The committees and executive bureaus of peoples' councils, unions of crafts, consumer, and agricultural production cooperatives, county, municipal, city, and commune councils for coordinating the activities of cooperative organizations, organs for banking financial control, and price control inspectorates, will exercise a systematic control, or if needed, will periodically analyze in terms of their functions, the conduct of small industry activities, and will take steps to rigorously respect the provisions of the present law.

Article 50. The Council for Coordinating the Production of Consumer Goods, the Council for Coordinating and Guiding Supply and Services Activities to the Population, and the Central Council for Coordinating the Activities of Cooperative Organizations, will assure according to legal provisions and to specialization and territorial interests, the unified coordination of activities in small industry

organized in accordance with the provisions of the present law, will supervise the manner in which these provisions are being followed, and in each domain of activity, will take compulsory measures for state and cooperative organs, as well as for production units, so that they may accomplish the tasks assigned to them.

Article 51. Ministries and other central organs which are responsible for units that produce consumer goods, must assure the full completion of the tasks assigned in programs for the development of consumer goods production throughout the economy, and included in the unified national plan for socioeconomic development.

Similarly, ministries and other central organs will take steps to organize in addition to industrial units under their control, shops or special departments for the production of consumer goods, which will assure the superior exploitation of reusable materials and other resources derived from production processes, in order to satisfy the needs of the population or to obtain raw materials, materials, and other products necessary for the economy and for exportation.

Article 52. On the date on which the present law becomes effective, Decision of the Council of Ministers No 1956/1970, regarding the use of work in the home for the manufacture of craft items and other products or projects, as well as any other provisions to the contrary, are abrogated.

This law was adopted by the Grand National Assembly at its meeting of 17 October 1980.

SERBIAN OPSTINAS SEEK TO RETAIN AID TO UNDERDEVELOPED AREAS

Appeal From Leskovac

Belgrade NEDELJNE INFORMATIVNE NOVINE in Serbo-Croatian No 1556, 26 Oct 80 pp 20-21

[Article by Dragan Jovanovic: "The South Is Knocking on the Door"]

[Text] Last week there were three reasons for NIN to speak once again about Serbia's underdeveloped south. First: the Executive Council of the Serbian Assembly, at the suggestion of the competent ministers, did not adopt the federal draft of the law on the underdeveloped regions of the republics and Kosovo, nor did this document make an appearance in sessions of the republic assembly last week. The second occasion was the debate on the republic fund for the underdeveloped in these sessions of the chambers of the Serbian Assembly. And the third and perhaps the strongest motive was the initiative from the Southern Morava region to obtain for this area "special treatment among the underdeveloped approximately equivalent to that afforded today to the province of Kosovo and the three underdeveloped republics."

In the spring of last year and again in the fall NIN took up the topic of the underdeveloped south which is knocking on the republic's door. At that time this reporter spent several days visiting that region and one local official made an acerbic joke: "It is a good thing that you have spent a few days here with us to see how poor this region of Serbia is, though you could have noticed it even if you had just sped through on the Simplon Express between Belgrade and Salonika."

Figures, Figures, ...

This October there are not many who feel like joking. Especially after certain reflections "up there in Belgrade," to the effect that Leskovac will drop out of the underdeveloped in the coming 5-year period. The Leskovac Opstina Assembly last month took up the Draft of the Agreement on the Bases of the Social Plan of the Socialist Republic of Serbia To Hasten the Economic Development of the Underdeveloped Region in the Period 1981-1985

along with suggestions concerning the agreement which had been sent by the Presidium of the Southern Morava Interopstina Regional Community. On 13 October the Presidium of the Leskovac Opstina Assembly submitted a written report in which it informed the competent people in the republic that "the proposal to omit Leskovac Opstina from the underdeveloped is untenable."

And it went on: "Leskovac Opstina has for more than a decade been pointing up its specific position, the concentration of problems and trends in economic and social development which necessitate special treatment in the republic. Probably the problems would have taken on less drastic form if the demands of Leskovac Opstina had received a responsible response in good time. In 1977 the competent authorities in the republic understood the seriousness of the situation in this opstina, the possible political consequences of such a situation and the importance of Leskovac' development to the faster development of the Leskovac subregion and the Southern Morava region as a whole."

Three years ago adoption of the law on the republic fund for the underdeveloped proclaimed the entire region an underdeveloped area, including Leskovac.

"Three years have passed since adoption of the law (on the fund)," the report goes on, "and the question arises: Has it been objectively possible in such a short period to overcome the problem of structure and underdevelopment in a large opstina that have accumulated for years and to create conditions for independent development? The fact is that this is impossible, and never has anything like that taken place in our economic history."

Then follow figures, not exactly new ones, but accompanied by the observation that even the republic authorities are using figures from 1978:

"In 1975 the per capita national income in Leskovac Opstina was 67.85 percent of the national income in Serbia proper, and in 1978 it was 67.18 percent. Or: the absolute difference in per capita national income between Leskovac Opstina and Serbia proper in 1975 was 6,399 dinars, and then in 1978 it reached 11,701 dinars, though during those 3 years the growth achieved was close to the relative growth in Serbia proper.

"One and only one conclusion can unambiguously be drawn from these figures: the relative decline of Leskovac Opstina's development had not been halted by 1978."

Then come comparative figures on (un)employment and the level of personal income, which also illustrate the "negative tendencies," and finally another warning of the "possibly very serious political repercussions" and "the engendering of a number of social problems."

In conclusion it proposes that when the executive council of Serbia and other authorities come to propose policy for stimulating the economic development of the underdeveloped regions in the republic they honor the demand that the Southern Morava region retain its status as an underdeveloped area for the next 5 years.

Why such great insistence that the entire region of 13 opstinas remain in the "club of 48 underdeveloped opstinas" out of the 114 opstinas in Serbia?

A Region at the Federal Level

"It is our assessment that the entire region has for years now been lagging behind the republic in its development, and the essence of our position is that those opstinas whose per capita national income is less than two-thirds of the republic average not be eliminated from the underdeveloped opstinas. So that even if Leskovac, Vranje or Vladicin Han should be a few percentage points above that limit, they should not be driven out of the group of underdeveloped opstinas, since these opstinas are the only thing that can pull the entire region out of its extremely unenviable position more rapidly. In any case this is a position in which all republic officials who have recently visited us have concurred," said Miroslav Zdravkovic, chairman of the Interopstina Committee of the League of Communists of the Southern Morava Region.

"We should not forget that this sensitive border region has a multinational population of more than 500,000 living in 698 settlements, that in 4 opstinas the national income is less than 25 percent of the republic average, which means that it is below the average of certain opstinas in Kosovo," Zdravkovic added.

"Does that mean that you believe that southern Serbia ought to be debated even at the federal level?"

"I really do not see why the Southern Morava region would not be debated in the Federation when the new criteria are established for measuring underdevelopment of regions within the republics and Kosovo," Zdravkovic answered.

Some of the figures presented last year by the republic bureau for social planning concerning per capita investments and the economic structure support Zdravkovic's thesis that the underdevelopment of southern Serbia in 1975 was "almost equal to the underdevelopment of Kosovo." The level of investment in 1971 was even lower than in Kosovo, and not much has changed since then.

The most responsible people in the Serbian Assembly understand the dissatisfaction of the southerners, but they feel that it is not realistic to "single out" a region in the republic and put it at the level of the underdeveloped republics and Kosovo, since this departs from the entire conception: "You cannot say that the underdeveloped are Bosnia-Hercegovina, Montenegro, Macedonia, Kosovo and ... the Southern Morava region."

What can be respected in the conclusion of agreements among the republics on financing the underdeveloped in the coming medium-term period is the "overall level of development of the republic." Then a specific estimate should be made of the size of the underdeveloped area in the republic. This area ought to be borne in mind when it comes to this republic's participation in the Federal Fund for Development of the Underdeveloped.

In the Serbian Assembly it is also felt that the conditions obtain for the present system of stimulation of the development of the underdeveloped to be amended in that direction. At this very time intensive talks are under way in the Federal Executive Council concerning the future development of the new system of stimulation, which is a continuation of the frank conversations begun this summer at Brdo near Kranj.

Thus even in the future the Southern Morava region can hope only for republic aid.

And what are the prospects at the moment in Serbia?

Contested Rates of Interest

Last week's debate on the republic fund for the underdeveloped in Serbia confirms certain old truths. Not so much because the decision on transferring the surplus income from interest of the Serbian National Bank to the republic fund was postponed. (The sum involved is estimated at between 300-400 million dinars.)

But those who opposed that solution immediately emerged--among them the Executive Council of the Serbian Assembly. Branko Mirkovic, chairman of the Serbian delegation in the Chamber of Republics and Provinces in the SFRY Assembly, says:

"The reason why I am against that decision is the awareness that the time has come to move from temporary and short-term measures to those real long-term ones.... In my opinion, then, there is one and only one conclusion to be drawn: these funds taken from the economy through the rate of interest can only be returned to that economy."

Rodoljub Stanic, chairman of one of the standing committees of the assembly, who defended the proposal that the republic fund was entitled to the income of about 400 million, immediately responded that it would not be a good thing to be "overscrupulous" when it comes to financing the underdeveloped regions.

After all, we should mention that the republic's intervention in the amount of 1.5 billion dinars to cover the losses of the Smederevo Steel Mill, which have now become a regular thing, had been adopted with hardly a word as one of the prior items on the agenda.

Underdeveloped Areas in the Period 1976-1980

1. Underdeveloped areas of Serbia proper (48 opstinas)
2. Opstinas having the status of underdeveloped areas of Serbia proper but receiving stimulation funds (11 opstinas)
3. Underdeveloped areas of the Socialist Autonomous Province of Kosovo

Nevertheless, the "scrupulous arguments" prevailed, and the fate of the bank interest and of the treasury of the republic fund for the underdeveloped was postponed until the end of the year.

Whatever the case, the south of Serbia will again this fall be knocking on the door of the republic. For the second time, for the third time.

Statistics on Underdeveloped Opstinas

Belgrade NEDELJNE INFORMATIVNE NOVINE in Serbo-Croatian No 1556, 26 Oct 80 p 20

[Text] The economy of Serbia proper in the period 1976-1980 set aside a total of 30,481.6 million dinars to stimulate the faster development of the economically underdeveloped republics and the SAP [Socialist Autonomous Province] of Kosovo. In that same period the republic provided 8,756.5 million dinars to stimulate the faster development of the economically underdeveloped areas within Serbia proper and 3,242.1 million dinars of supplemental funds to opstina budgets.

If in the coming medium-term period the same proportions are maintained in appropriations for these purposes, the economy of the republic would be required to furnish more than 90,000 billion dinars for the faster development of the economically underdeveloped republics and the SAP Kosovo and about 15,000 million dinars to stimulate the faster development of economically underdeveloped areas within the republic and about 4,500 million dinars of supplemental funds to opstina budgets.

A study by the Economics Institute in Belgrade concerning the situation in 1975 said, among other things: Of the 84 underdeveloped opstinas in Yugoslavia 29 are in Bosnia-Hercegovina and have a population of 868,073. In Serbia there are 45 of the most underdeveloped opstinas, and their population is 1,550,039; 29 of these opstinas, with a population of 728,202, are in Serbia proper, and 16, with a population of 821,837, are in Kosovo. In Croatia there are 6 of the most underdeveloped opstinas, and they have a population of 173,163. Macedonia has 2 such opstinas, with a population of 32,340, and Montenegro also has 2, with a population of 27,928, while Slovenia and Vojvodina do not have any such opstinas.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

EAST-WEST ECONOMIC RELATIONS SINCE HELSINKI ANALYZED

Stuttgart OSTEUROPA-WIRTSCHAFT in German Vol 25 No 3, Sep 80 pp 165-198

[Lead article (names of authors of individual studies given in text): "From Helsinki to Madrid: The Development of East-West Economic Relationships With Regard to the CSCE Basket II Resolutions." Passages in slantlines printed in italics]

[Text] Preliminary Remarks and Overview

In ratifying the Final Act of the Helsinki Conference on Security and Cooperation in Europe, the participant states agreed to hold at regular intervals successor conferences so as to facilitate an exchange of views on the implementation of the resolutions of the Final Act and on the overall development of the process of detente. Against the background of the considerable political and economic changes in East-West relations that have occurred since 1975, the second successor conference has been scheduled to convene in Madrid. However, in spite of the increasing difficulties that have arisen in the relations between the Western industrialized countries and the Soviet Union, efforts are being made--at least in the field of economic, scientific, technological and environmental cooperation, the so-called CSCE Basket II--not precipitately to abandon the principle of "business as usual" or at least to keep the other CEMA states out of the political aggravations affecting the trade relations.

Conversely, the East European states have likewise been signaling their continued interest in the maintenance or improvement of economic relations. The Soviet Union, too, is unlikely to wish for a deterioration of the economic relations between its CEMA partner states and the West, since in such a case it would have to make greater material contributions to the solution of these countries' politicoeconomic problems. Furthermore, the national economies of East Europe could assume the role of an intermediate importer, at least for certain Western products and technologies.

In view of these considerations, a review of the development of the economic relations between the individual CEMA countries and the industrialized West during the 4½ years after the ratification of the CSCE Final Act and the attempt to evaluate the developmental possibilities of these countries' trade with the West in the 1980's appear to be of considerable interest.

Regarding the Soviet Union, the CSSR, Hungary and Romania, the Politics and Science Foundation (Stiftung Wissenschaft und Politik, Forschungsinstitut fuer Internationale Politik und Sicherheit [Science and Politics Foundation, Research Institute for International Politics and Security, 8026 Ebenhausen]) ordered national analyses of this type, the results of which are presented in the following in abridged form. In addition to these national studies, the Foundation ordered three studies on the possibilities of scientific cooperation between the Federal Republic of Germany and the Soviet Union, on all-European cooperation in the energy sector and on the development of the transportation sector within CEMA. The abridged versions of these studies are presented here as well.

The individual studies were produced by the following authors:
Soviet Union: W. Beitel (Stiftung Wissenschaft und Politik)
Czechoslovakia: F.-L. Altmann/J. Slama (Osteuropa-Institut Muenchen [Institute for the Study of Eastern Europe, Munich])
Hungary: A. Inotai (Institute for World Economics, Budapest)
Romania: N. Danos (Stiftung Wissenschaft und Politik)
Scientific cooperation: J. Noetzold (Stiftung Wissenschaft und Politik)
Cooperation in the energy sector: F. Mueller (Stiftung Wissenschaft und Politik)
Transportation: W. Gumpel (University of Munich)

Economic Relations Between the Soviet Union and the Western Industrialized Countries and Possibilities Regarding Future Cooperation

The Soviet Union's military intervention in Afghanistan and the reaction of the United States endanger the results of East-West economic relations in Europe. These events also reactivated the question concerning the interrelationship between Eastern trade and Ostpolitik. Even in the past, East-West trade had been affected by the changes in the political climate between East and West; these impulses have had both an intensifying and a limiting effect. At present, the West is compelled to reexamine the basic positions of the policy of detente hitherto pursued and to ask itself whether this policy was possibly based on an illusory perception of Soviet objectives. For example, in regard to their view of the policy of detente, certain political groups in the West possibly cherished the illusion that the Soviet Union had abandoned the idea of a global enforcement of their model of supremacy. Consequently, the West is called upon to reformulate the rational foundations of this policy and thus to make it acceptable again to a broad range of the political spectrum.

The present study attempts to record the results attained in the past decade in the relations between East and West and also to point out the aspects that make a continuation of the normalization process between East and West appear desirable in the 1980's as well; the study ascribes to the economic relations--a field characterized by obviously identical interests--a function providing impulses and conducive to the continuation of the process of detente.

In the 1980's as much as in the preceding decade, the economic relations between the Soviet Union and the Western industrialized countries will depend on the partners' readiness to contribute to the solution of the acute political problems concerning East-West relations. The CSCE successor conference--scheduled to convene in Madrid in November 1980--offers them the opportunity to do so. Thus this conference can be said to be as important for the future economic relations between East and West as was the Helsinki CSCE for the economic relations of the 1970's.

During the 1970's, the Soviet Union rapidly expanded its trade with the West. However, the growth rates were not evenly distributed over this period: In the first 3 years, the annual commodity turnover stagnated at the R 5-6 billion level; subsequently, up to 1976, it developed at an unprecedented rate, showing a 3-fold increase. In 1976, there began a phase of consolidation--with an annual Western trade turnover of approximately R 19 billion--which was superseded only last year by another turnover increase.

Due to the rapid expansion of the trade with the West, the Western industrialized countries increased their shares of Soviet foreign trade. These shares increased from 25 percent in 1970 to a maximum of 38 percent in 1976, subsequently dropping back to 29 percent (1979). All told, during the 1970's the regional structure of Soviet foreign trade underwent changes favoring the West. In the course of this process of regrouping, the Federal Republic of Germany was able to increase its share of Soviet foreign trade. And conversely, the Soviet Union succeeded in the 1970's in doubling its share of the foreign trade of the Federal Republic of Germany.

The intensification of the Soviet Union's trade with the West during the period under discussion came about on account of the /difference in the dynamics of Soviet Western imports and exports/. While the first half of the 1970's was characterized by an increase in imports from the West, in the second half the Soviet Union was able to expand its exports to the West. Last year (1979), for example, the Soviet Union for the first time showed a trade balance surplus in its exchange of goods with the FRG.

Occasionally, the Soviet Union has been expanding its imports from the West far beyond the financing limits set by Western exports and has to this end taken up /loans/ in the Western credit markets. However, the increased borrowing by the Soviet Union should not be viewed as a sign of decreasing export capacities. The oil price rise of 1973--along with the nearly riskless projection of future price hikes--created the preconditions for growing export proceeds; consequently, the borrowing did not involve any unacceptable impairment of the Soviet Union's independence in the realm of foreign trade.

The borrowing was furthered by the Soviet Union's increased willingness to expand the export sector through extensive capital goods imports so as to

be able more comprehensively to utilize the international division of labor for its own growth policy. Finally, the changes in the political atmosphere between East and West created additional impulses for the credit financing of the technology transfer to the Soviet Union.

As regards the /extent of the indebtedness/, the only data available are the estimates of Western credit banks. According to these estimates, during the 1970's the Soviet gross hard-currency indebtedness increased from approximately U.S. $2 billion (at the end of 1970) to approximately $16 billion (at the end of 1979). The greatest increase occurred during the period from 1975 to 1977. The determining factor in regard to an evaluation of the foreign trade borrowing is the net indebtedness, the difference between the claims of Western creditors vis-a-vis the Soviet Union and the claims of the Soviet Union vis-a-vis foreign institutions. According to U.S. estimates regarding the gold and arms sales and the returns from services (e.g. marine and rail transport), there was a relatively minor net indebtedness of approximately U.S. $4 billion (end of 1978).

As regards the development of Soviet borrowing during the 1970's, the striking aspect is the consolidation that has been achieved since 1977: A few years after an enormous foreign debt increase, the Soviet Union has stabilized its imports at the level attained and has at the same time been able to increase its hard-currency export proceeds.

On account of the intensified efforts that have been made in the last few years so as to reduce the imbalance in the trade with the Western industrialized countries, the German-Soviet trade has been stagnating and German exports actually have shown a slight decline. However, due to the consolidation of the trade balance that was achieved by the end of the 1970's, there is the possibility that imports from the West may rapidly expand on the basis of new loans, without the Soviet Union having to abandon its goal of foreign-economic independence. Nevertheless, the question is whether the expansion of Western trade will be assured even if the West is not prepared to grant credit.

At the beginning of the 1970's, the Soviet Union's trade with the West was restricted by unfavorable /terms of trade/ for the Soviet export supply of raw and basic materials. Likewise, the reformist attempts within the Soviet national economy that were intended to intensify the orientation toward exports did not bring about any short-term improvement of the situation regarding export proceeds. It was only the sharp increase in the price of the most important Soviet export product, petroleum, that proved to be the turning point. The increase in the price of oil and subsequently, in the prices of other energy sources as well was considered irreversible in the Soviet Union. Thus, in the mid-1970's, the Soviet Union could justly expect a steady increase in export proceeds, even though the goal of gradually changing the export commodity structure by increasing the share of "intelligent" goods could be implemented only slowly. Consequently,

for the exploitation of energy deposits in Siberia, the Soviet Union increasingly drew on Western capital and know-how so as to speed up the start-up of new capacities, especially since the specific risks of capital import in the raw and basic materials sector could be reduced through long-term delivery contracts. However, the development of the /petroleum export volume/ has given rise to the question whether the capital invested will be sufficient--in view of the country's own needs and the requirements of the CEMA trade partners who are dependent on oil imports--to make available sufficient quantities for exports to the West, in order to be able to finance increased imports from the West in the 1980's.

The overall decline in oil exports notwithstanding, the Soviet Union has been obtaining annually increasing hard-currency returns. Since the Soviet Union can justly expect the prise rise to continue, this trend can in the medium term be maintained with the present export volume of approximately 90 million tons of oil. Should the Soviet Union during this period be able to follow the example of the Western industrialized nations and to sever the link between economic growth and oil consumption, its participation in the international division of labor would be conceivable even on the basis of oil exports.

On the other hand, a U.S. prognosis concerning Soviet oil production and the resultant export possibilities and import requirements is based on the assumption that it will be impossible--at least in the medium term--to make economic growth independent of oil consumption and that the Soviet Union does not have at its disposal sufficient oil substitutes. Thus, with demand increasing as a result of economic growth, the fact that oil production will be stagnating until 1985 is bound to make the Soviet Union--as early as the first half of the 1980's--a net oil importer. At present, it is difficult to tell whether the actual development will follow this forecast; in view of the Soviet Union's increasing awareness of the problem, it is likely to be less dramatic.

In the past decade, the Soviet Union and the Western industrialized countries developed new forms of international cooperation; in this respect, emphasis was placed--with a view to the trade volume thus attained--on long-term and comprehensive /compensation agreements/ modeled after the pipe-natural gas agreements, i.e. "compensation agreements of the Soviet type." These agreements represent an order volume of approximately U.S. $8 billion and will by the mid-1980's win the Soviet Union U.S. $4 billion worth of foreign currency per year, thus providing a certain compensation for the potential decline in oil export proceeds. For the current year (1980), the compensation commodity share of Soviet exports to the West is assumed to be as high as 35 percent.

The Soviet Union regards these agreements as an especially suitable form of international cooperation, since they permit--among other things--the credit financing of projects of national-economic dimensions and at the same time guarantee future export profits, thus from the outset insuring

repayment of the loans. The Western partner is primarily interested in the Soviet market for capital goods. Aside from the fact that these features offer certain advantages in regard to employment policy, the scope and the long-term nature of the agreements are problematic, since they impede adjustment to the rapid changes in the basic conditions on Western markets and since the agreements thus occasionally overtax the absorptive capacity of these markets. In the Western view, the applicability of these agreements is therefore restricted to fields such as the energy supply sector--fields characterized by continuing, long-term demand. The agreements are problematic also from the point of view of structural policy, since they are one-sidedly oriented toward big industry and require state support, e.g. in regard to credit insurance.

So far, the Soviet Union has not agreed to foreign /direct investments/, a proven instrument of the international technology transfer. On the other hand, the /cooperation/ between foreign and Soviet industrial enterprises represents an organizational form that does not run counter to the basic principles underlying the Soviet economic system. The implementation of concrete projects has so far been thwarted by the differences in production standards and by the risks resulting from nonobservance of delivery dates.

In the past, it was always safe to assume that the limitations of Soviet trade with the West resulted above all from the limited capacities of the Soviet export sector; at present, however, there is the danger that a stagnation of this trade may be brought about by the politically motivated economic sanctions of the Western industrialized countries. Thus the future economic cooperation between East and West depends on the success of the efforts toward solidarity, which would make obligatory for the Western industrialized countries the United States' /embargo policy/ vis-a-vis the Soviet Union.

The United States justifies the necessity to regulate the transfer of technology to the Soviet Union by pointing out that the export of goods of military applicability could boost Soviet armaments and that the technology transfer could improve the Soviet Union's economic capacity in general and thus indirectly support the country's war industry. According to this argumentation, the embargo policy serves security-related objectives. Likewise, the present wheat embargo is intended to demonstrate to the Soviet Union that the military intervention in Afghanistan will not be accepted. In this regard, it serves a political purpose as well.

The /differences of opinion/ among the Western industrialized countries concern the definition of goods of strategic applicability. While the United States holds that this category includes all goods that are apt to increase the Soviet Union's economic potential, the West European countries are inclined to subject to an embargo only goods distinguished by immediate military applicability. Even if the countries could agree on the desirability of categorically withholding certain goods from the Soviet Union as a potential military enemy, there remain differences of opinion concerning

the /practicability/ of a comprehensive export ban. To some extent, the disagreement between the United States and the Western industrialized countries is attributable to the differences in regard to trade interests vis-a-vis the Soviet Union. In the case of the United States, the interest is no more than marginal, thus allowing stricter export controls. The West European countries and Japan, on the other hand, are much more dependent on exports of capital goods and thus do not want to dispense with the potentially large Soviet market.

Even though an agreement of the Western industrialized countries on the basis of the United States' embargo policy is unlikely, some /potential consequences concerning East-West relations/ should be mentioned here. Such an agreement would result in economic losses for the West in regard to exports of industrial goods and--in the event of a Soviet countermove--in regard to imports of raw materials and energy sources as well. However, the economic losses would be unequally distributed among the United States and its partners. A consistent embargo policy would intensify the Soviet Union's present efforts toward self-sufficiency and direct the Soviet Union toward the "socialist world market", i.e. it would effect a reorientation of the trade flow, directing it to the CEMA countries. As a result of such an acceleration of CEMA integration, the CEMA's latitude in the field of foreign trade would be further reduced.

In participating in the international division of labor, the Soviet Union hopes to derive benefits in regard to time savings and cost reduction in the process of industrialization. The trade relations with the Western industrialized countries are of special importance, since the technology transfer from these countries can be expected to provide the most effective impulses for productivity improvements in the Soviet economy.

Technological progress must be promoted above all through reform measures in the country's own economic apparatus. The Soviet leadership has so far refrained from radical reform measures; consequently, the technology transfer from the West can be said to be economically significant as well. Nevertheless, foreign trade will remain just one among several instruments for improving the Soviet Union's economic capacity.

At present, the Soviet Union--like the other industrialized states--is confronted with a scarcity trend in regard to the production factors. The current problems in agriculture and in the energy sector are aggravating the problem concerning allocation of the investment funds, which are no longer expanding rapidly. In the 1980's, the Soviet Union will no longer be able to step up employment in the country's key industrial production regions. Thus the country will reach the limits of the traditional growth policy of annually increasing production factor utilization. Aside from the growing need for a more efficient organization of the economic apparatus, there will be an increased need in the 1980's to import labor- and material-saving technologies from the Western industrialized countries.

During the 1970's, the development of East-West trade paralleled the normalization of political relations between East and West. In retrospect, one can discern periods, in which political as well as economic factors were predominant and which thus document the /general interdependence of politics and economics/. The normalization of East-West relations began as a result of economic contacts in Europe. The United States joined in this process after some delay and tried to further the process of political normalization through intensified economic contacts. The present deterioration of the political climate in turn affects the economic relations and possibly restricts the possibilities concerning a future intensification of trade in the 1980's.

The Soviet Union, too, recognizes the interdependence of economic and political relations. Thus the economic objectives concerning modernization of the Soviet national economy have provided impulses in regard to an improvement of the political relations with the West. And conversely, it has been pointed out that political factors determine the direction and intensity of the trade relations. Thus, in the 1970's political detente laid the foundations for the rapid development of economic relations with the West.

On account of the interdependence of economic and political relations, there is a chance that along with the intensification of the economic relations with the Soviet Union it may also be possible to consolidate peace in Europe. But this interrelationship is not so narrow as to allow a one-sided enforcement of political objectives by economic means. If the various operational levels of international politics were given a maximum degree of mutual independence, the regional normalization that has been attained between East and West, e.g. in Europe, could be maintained and consolidated. The indivisibility of the policy of detente remains an international objective yet to be attained.

The Foreign Trade Relations of the CSSR With a View to East-West Cooperation

The present study presents the economic determinants of the CSSR's economic relations with the West in the 1970's and 1980's and evaluates them from the point of view of the Helsinki resolutions concerning the trade relations between East and West. The results of the study can be summarized as follows:

The military invasion by the Soviet Union in August 1968 interrupted a development in the CSSR that politically and economically could have made the country a vanguard of the policy of detente and of East-West relations. The subsequent so-called normalization policy greatly restricted Czechoslovak initiatives regarding expansion of the relations with the West. Official CSSR statements on the Final Act and on the problems concerning Basket II are in accord with the collective resolutions of the Warsaw Pact states.

During the second half of the 1970's, the CSSR's economy went through a phase of /steadily slowing growth/. The manpower utilization and investment growth rates declined, as did the rise in productivity. The increase in total factor productivity amounted to barely 50 percent of the level attained during the first half of the 1970's. Moreover, since 1975 the growth of the national income produced has clearly been exceeding the growth of the national income used--a phenomenon directly related to the deterioration of the CSSR's foreign trade position: Since the import price rise is more rapid than the increase in export prices, it is necessary steadily to expand exports so as to cover the cost of imports. In the last few years, it was only through extending its foreign debt that the CSSR has been able to prevent stagnation of consumption and investment.

During the second half of the 1970's, the CSSR's /foreign trade/ was clearly marked by the above-mentioned deterioration of the "terms of trade." Although the price increases included finished goods as well, the much more rapid rise in the prices of raw materials and fuel led to increasingly unfavorable trade balances, what with the CSSR's given dependence on imports in this sector.

In this regard, the most striking aspect is the fact that the "terms of trade" deteriorated not only vis-a-vis the hard-currency countries (Western industrialized countries and developing countries), but also vis-a-vis the CEMA countries--the principal suppliers of raw materials and fuel. In order to be able to pay for the increasingly expensive raw materials, the CSSR had to expand the machinery exports, its main source of income, and it had to expand these exports more rapidly than was justified in light of the real increase in raw material imports. The country's own production could not meet these growing demands to the extent desired; thus the export and domestic investment sectors were faced with a shortage of products of the machine building industry.

Consequently, the CSSR has been compelled--especially in its trade with the Western industrialized countries--to resort to exports of raw materials and consumer goods so as to be able to meet its liabilities. This situation has given rise to difficulties in regard to domestic supplies. At the same time, the CSSR has pointed out that as a result of the uncertain conditions in the Western markets the country is faced with increasing protectionism and complex import licensing procedures, especially in regard to its traditional export groups, and that its efforts toward expansion of trade with the West are thus severely restricted.

Aside from the expansion of the general trade relations, the Final Act of the Helsinki Conference made reference above all to the /more intensive forms of economic cooperation/. The pertinent basic conditions concerning the institutional and legal aspects are laid down in inter-state agreements on economic cooperation. At the time the Final Act of the Helsinki Conference was ratified, there were 10 such skeleton agreements between the CSSR and the Western participant states; among the CEMA countries, the CSSR

thus was in last place. Since that time, only two new inter-state agreements have been concluded (with the Netherlands and Spain); two agreements on economic cooperation already in force (with Belgium/Luxembourg and with France) have been revised and expanded.

At the beginning of the 1970's, a new law (1972) on economic /cooperation/ with foreign countries had resulted in the termination of 20 cooperative agreements between Czechoslovak enterprises and Western firms. Thus, at the time of the Helsinki Conference, only the GDR had fewer cooperative agreements on the company level than the CSSR. Shipments of goods carried out on the basis of cooperative agreements accounted for just 1 percent of the CSSR's total exports to the West. Although the stricter licensing procedure stipulated by the 1972 law was eased in October 1975 and although new material incentive measures were adopted for the cooperating Czechoslovak enterprises, even now there are no more than 40 cooperative ties, which in 1979 accounted for just 1.6 percent of the CSSR's exports to the West. Four West German companies account for nearly 50 percent of the total monetary value of the CSSR's cooperative transactions with nonsocialist countries. In all, FRG firms account for nearly four-fifths of the turnover resulting from the CSSR's cooperative agreements with the West. Another indication of the CSSR's low regard for cooperative relations with Western countries is the fact that only one compensation agreement (with an Austrian firm) has been concluded.

Foreign capital is barred from /acquiring shares/ in CSSR enterprises. Conversely, a government decree passed in 1973 allows CSSR enterprises to acquire shares in foreign firms. So far, however, participation in production enterprises has been limited to developing countries. Likewise, in regard to participation in commercial firms or the establishment of mixed companies, the CSSR has shown itself to be much more reserved than the other CEMA countries. In the years after the Helsinki Conference, there have only been two cases of cooperative ventures in third countries involving a Czechoslovak and a Western enterprise; in both of these cases, the Western partner has been an FRG firm.

The /slowing of economic growth/ in the CSSR is likely to persist in the 1980's. The manpower shortage will not be alleviated. In view of the large investments required in the 1980's in the energy and infrastructure sectors, compensation by increased capital investment will not be feasible. With world market prices of raw materials and fuel steadily rising, the relative scarcity of raw materials will not only greatly affect the CSSR's balance of payments, but also block growth insofar as cutbacks in energy and raw materials consumption become imperative. In the next few years, a large part of the investment volume will be needed for the accelerated expansion of the nuclear power plants. But it is not only domestic factors that account for the strong concentration on the development of nuclear power technology. Next to the USSR, the CSSR will be the biggest producer of nuclear power equipment in the 1980's and by 1990, the country is to supply approximately 50 percent of the nuclear power plants to be

established in the CEMA countries outside the Soviet Union. This will inevitably restrict expansion of CSSR industry in other sectors.

In view of the CSSR's unfavorable foreign trade position and the general slowing of economic growth in the CEMA countries and in the Western industrialized countries, a /marked decline in the growth rate of CSSR foreign trade/ is to be expected in the 1980's. The CSSR will continue its efforts to reduce its trade balance deficit vis-a-vis the West by imposing import restrictions, since its possibilities regarding expansion of Western exports are extremely limited.

Likewise, as regards the relations with the CEMA countries, above all with the Soviet Union, the CSSR is likely to try to reduce its liabilities. On the other hand, the CSSR must try to maximize its imports from the CEMA area, since in accordance with the sliding-price clause the country still enjoys here certain price advantages. Under these conditions, an increased economic and political dependence on the Soviet Union will probably be unavoidable, since the CSSR obtains most of its raw material and fuel supplies from the Soviet Union; moreover, the 10-year economic agreement that was recently concluded by the two countries provides for still closer cooperation in certain key industries.

In connection with the /Madrid successor conference/, the following factors appear to be significant in regard to the CSSR: On account of the above-mentioned developments, the CSSR does not have much latitude in regard to expansion of its trade relations with the West. Special activities in regard to the implementation of Basket II provisions are not and never were very likely. In comparison with the other CEMA countries, the CSSR has so far shown the least willingness to promote cooperation on the company level or to establish "joint ventures." Likewise, the changes in the economic control system that are to be made in 1981 are not indicative of any marked expansion of the enterprises' freedom of action, especially not in regard to the trade with the West.

The administrative inflexibility impedes even simple contra transactions, insofar as performance and counterperformance fall under the jurisdiction of different foreign trade organizations. Moreover, the regulations concerning establishment of permanent manufacturer's agencies are restrictive. The existing channels for establishing contacts on the intermediate administrative and company levels are likewise insufficient. The obligatory interposition of a frequently uninterested foreign trade organization impedes establishment of more intensive economic relations. The distrust toward simple market research has had an extremely inhibitory effect. Marketing in a broader sense is relatively underdeveloped in the CSSR. In the years since the Helsinki Conference, no progress has been made in regard to contacts with CSSR economic research institutes and individual economists. This impedes any objective evaluation and exchange of views.

The Foreign Trade Relations of the People's Republic of Hungary With a View to East-West Relations

In the growth process of the Hungarian economy, the foreign trade relations play an increasingly important role. In the last 10 years, the GNP increase (1 percent) was accompanied by a 1.75-percent increase in exports and a 2.5-percent rise in imports. While the economic relations with the OECD countries were extended, the CEMA countries will remain Hungary's principal trading partners. For the CEMA integration and the economic relations with the Western industrialized countries are interdependent elements of Hungary's foreign trade policy.

The divergent development of Hungary's imports and exports resulted in a /trade balance deficit/ that up to 1978 showed a rising /merchandise traffic deficit/. The foreign trade with the OECD countries accounted for 75 percent of the total foreign trade deficit. Whereas between 1970 and 1978 the OECD countries' share of Hungary's exports increased only by 3.2 percent (from 27.2 to 30.4 percent), the OECD share of total imports rose by 12.5 percent (from 27.1 to 39.6 percent). This development was due above all to the increase in the import volume, not to changes in the "terms of trade."

As regards imports from the socialist countries, on the other hand, the price increases accounted for over one-third of the appreciation and the increase in imports from developing countries is entirely attributable to price hikes. Here the trade deficit is reduced, since the volume of exports to the CEMA states and to the developing countries was expanded considerably.

As is the case in the other CEMA states, machines and equipment constitute only a small share of Hungary's exports to the OECD countries. This is due to the fact that in the past Hungary's developmental policy was not primarily concerned with the establishment of production facilities for commodities that could have been sold in the OECD market. To be sure, the modernization of Hungary's commodity assortment during the 1970's resulted in changes: The export share of industrial consumer goods increased considerably and since 1973, exports of machines and equipment have likewise been slowly expanding.

As regards the trade relations between the People's Republic of Hungary and the OECD countries, the /Federal Republic of Germany/ plays an increasingly important role. The FRG has for some time been the second most important supplier of the Hungarian economy and in 1978 it was the second largest buyer of Hungarian products. For a number of years, imports from the FRG have accounted for approximately 40 percent of Hungary's machinery imports from the OECD area. The FRG on its part receives over 30 percent of Hungary's exports of industrial finished goods and machines to the OECD area.

For many years, the bilateral exchange of goods has been marked by a considerable Hungarian deficit. The FRG accounts for one-third to two-fifths of the Hungarian foreign trade deficit in the OECD trade and for approximately 30 percent of Hungary's total foreign trade deficit.

The /share of finished goods/ of Hungary's exports to the FRG has been increasing steadily and presently constitutes 50 percent of total exports; however, the finished goods exports comprise a great many articles that are produced by the so-called structurally weak branches in the FRG as well and that therefore are subject to import quotas and customs duties. Consequently, maintenance of this export structure would introduce an element of instability into the trade relations. There has still been no increase in the share of those Hungarian commodity exports to the Federal Republic that on the one hand are in great demand in the FRG and that on the other hand could benefit from the competitive advantages of the Hungarian economy. However, this qualification notwithstanding, finished goods constitute a larger share of Hungary's exports to the FRG, as compared to the exports to the FRG from the other CEMA states.

This indicates that the export-oriented policy adopted by the People's Republic of Hungary is producing results and that the /cooperation/ between Hungarian and West German enterprises has served to modernize Hungary's export structure and to increase the country's export volume. However, both the cooperation on the company level and Hungary's purchases of Western licenses have led to a situation, where the goods produced on this basis are sold primarily in Hungary or in the other CEMA states rather than in Western markets. This is attributable to restrictive practices of the Western enterprises (no cooperation or l[illegible] in regard to products in the introductory or growth phase, prohibition of sales in Western markets) and to the CEMA markets' greater absorptive capacity for goods that in the Western industrialized countries have for some time been part of the standard assortment.

During the 1970's, the intensification of the trade relations with the OECD countries also led to the /establishment of Hungarian enterprises (or enterprises involving Hungarian participation) in the West/. These enterprises are primarily concerned with the marketing of Hungarian products in Western countries. In the last few years, a number of production enterprises have been established as well; however, their activities have not progressed past the initial stages. Like the cooperation agreements, the Hungarian business ventures are concentrated on Austria and on the Federal Republic of Germany.

According to the legal regulations that were passed in the fall of 1972 and significantly modified in 1977, /direct investment of foreign capital in Hungary/ is permissible. So far, however, only three joint enterprises have been established; this seems to indicate that this form of cooperation has not yet progressed past the experimental stage. However, it appears that in the 1980's the conditions will be more favorable in regard to the activity of joint ventures in the People's Republic of Hungary.

There are also a few examples of /cooperation on third markets/--especially of joint ventures in developing countries. On account of the good results achieved so far in the bilateral cooperation between Hungarian and OECD firms, conditions are favorable in regard to the expansion of trilateral cooperation. Among the positive factors to be mentioned in this respect are Hungary's research, planning and development capacities, certain accounting-related factors, and political reasons.

Generally speaking, it is safe to say that the form of economic relations that go beyond foreign trade proper have initiated a closer and more protracted cooperation that could help stabilize the economic cooperation even in politically or economically difficult periods.

In the /second half of the 1970's/, the People's Republic of Hungary found itself in an unfavorable situation in regard to foreign trade. The deterioration of the "terms of trade" and the decline in exports aggravated the foreign trade imbalance. Consequently, the problems pertaining to foreign trade are likely to remain for some time a key factor in Hungary's economic policy. Reduction of the foreign trade imbalance is the primary objective; this goal is to be attained through the /strategy of forced exports/ that was formulated in 1977 and that has since been gradually implemented. For Hungary, this means on the one hand abandonment of a growth-oriented economic policy and on the other hand changes in the production structure with increased emphasis on competitive advantages.

In order to enforce these changes in the production structure, Hungary intends to discontinue the protective measures shielding its enterprises from world market influences. To this end, the country has developed an economic-political control system, the key element of which is the /gradual adaptation to world market prices/ in those economic sectors that are involved in the international division of labor. This arrangement affects approximately 35 percent of the total production of the People's Republic of Hungary. Enterprises that export to convertible currency areas are granted tax relief or adaptation subsidies. The /right of direct exports/ is increasingly granted to production enterprises. Within the framework of so-called inter-sectoral development firms, the foreign trade enterprises are to adopt export-promoting measures.

Increased Hungarian exports to the OECD countries can be expected in the following sectors, in which competitive advantages can be brought into play: agriculture and related food industry branches, aluminum production, electric machine building, electrical engineering, instrument building, the pharmaceutical industry, refined chemicals, and some branches of the machine building industry. However, in order to insure the success of an export policy oriented toward exploitation of competitive advantages, it will be necessary further to develop the economic control system and further to extend more intensive forms of cooperation with Western enterprises.

Aside from the above-mentioned production sectors, there are /other possibilities regarding the development of economic relations between Hungary and the West/:

--Hungary's geographic location offers possibilities of overcoming infrastructure-related problems in connection with the expansion of trade between West Europe and the Near East and between Western countries and the East. The participation of a number of OECD countries in highway construction and railroad modernization in Hungary could contribute to a smooth handling of the increased merchandise volume.

--In the science and research sectors, Hungary has at its disposal a considerable pool of personnel that can be used at lower wages, as compared to the OECD area.

--Likewise, the Hungarian tourist industry offers wage-related (but also natural) advantages that could be exploited through joint expansion of the tourism-related facilities (not least tourism for medical purposes).

--As regards trilateral cooperation in "threshold countries", Hungary can draw on its development- and system-related experience (instruction, specialized training, health services, etc.).

To what extent it will be possible to utilize such potential assets for economic cooperation depends on a number of factors. In this connection, one should point out the following:

--The export-oriented developmental strategy of the People's Republic of Hungary has been brought into play at a moment, when the world economy has become less stable--a situation likely to continue for some time. The /world-economic uncertainties/ impede the transition from the traditional import-substituting developmental policy to a real--mental as well as practical--emphasis on exports. To be sure, the greatest danger to the Hungarian economy lies in a rigidification of the present production structure and the resultant weakening of the export potential, not in a higher or lower degree of self-sufficiency in regard to raw and basic materials. Nevertheless, one cannot rule out the possibility of frequent plan changes that could counteract a long-term economic strategy. For example, even though the expansion of exports to countries with convertible currency has since 1975 been given priority, the most important investments made since then have not been oriented toward that objective.

--In order not to increase the trade balance deficit, /imports from convertible currency regions/ are not to be expanded. The 1980 plan even stipulates that the Hungarian machinery imports from these countries be reduced by 15 percent--despite the fact that the modernization and reorganization of production with a view to exploitation of competitive advantages would necessitate increased imports from the OECD countries.

Under these circumstances, stabilization of the economic relations between the People's Republic of Hungary and these countries depends to a great extent on developments in the OECD countries. The slow-down in the OECD countries' economic growth, the uncertainties in regard to the structural changes in West Europe's industry, and the protection of structurally weak branches impede the desired reduction of the foreign trade imbalance through an export-oriented foreign trade policy.

The following measures would serve to support Hungary's foreign trade policy:

--The preferential agreements of the EC restrict Hungary's exports to the EC. A skeleton agreement between the EC and CEMA probably could partly eliminate this drawback.

--In regard to the cooperation on the company level, the Western partners should adopt a less restrictive position in regard to markets and the transfer of technology.

--The credit-granting policy should honor Hungary's export-oriented economic policy, i.e. it should make allowance for the fact that this policy creates the preconditions for repayment of the loans.

Implementation of these measures could boost mutual trust and stimulate the economic relations. Closer economic relations could make these relations less vulnerable to sudden policy changes; otherwise, political changes would freeze even those processes that are largely governed by their inherent economic laws.

The Foreign Trade Relations of the Socialist Republic of Romania, in Particular With the Federal Republic of Germany, With a View to East-West Cooperation

For the Socialist Republic of Romania, the economic relations with the Federal Republic of Germany are of special importance. This is evident from the very fact that the FRG is Romania's second most important foreign trade partner. But how great is the FRG's interest in economic relations with Romania? If the yardstick is Romania's share of the FRG's total foreign trade turnover, it must be considered small. But if one views the relations with Romania within the framework of all-European cooperation, this interest assumes another dimension. Romania has always been a vanguard of sorts in regard to the development of relations between the Federal Republic and the other CEMA countries. This goes above all for the establishment of diplomatic relations in 1967, but also for the establishment of a mixed government commission for economic cooperation and for the inclusion of West Berlin's research potential in an agreement on scientific and technological cooperation. Romania wants to balance its foreign trade relations with the most important regional groups, the CEMA countries, the Western industrialized countries and the developing

countries. This objective also reflects the desire for insuring a maximum degree of political independence. Viewed from this angle, the development of the policy of detente is of extraordinary importance to Romania, since the Romanians feel that equilibrium between the superpowers reduces hegemony-related pressure on small and medium-size countries.

As regards its /domestic economy/, Romania continues to adhere to /disproportionate/ growth and central economic control, and this has impeded implementation of some economic reform measures. Nevertheless, in pursuing this economic policy, the country has been able to maintain a high rate of economic growth that by far exceeds the growth rate of the other CEMA countries. However, the plan targets have not been met, which is due above all to the changes in the international energy markets. In order to protect itself from these influences, the country has drawn up an energy program that is to insure self-sufficiency in the energy sector by 1990.

A great deal of attention is directed to the /foreign trade relations/. In spite of the occasional import restrictions intended to improve the negative foreign trade balance, the foreign trade turnover has been increasing continuously. In terms of regional emphasis, the socialist states account for approximately 50 percent of the country's foreign trade, while the developed free-market economies and the developing countries account for approximately 25 percent each. Although Romania wants to avoid economic dependency on the other CEMA countries, these countries are granted--on account of a number of advantages ranging from favorable geographic location to the possibility of saving convertible foreign currency—a 40-percent share of Romania's foreign trade turnover. It is noteworthy that in the trade with the CEMA countries the volume of products resulting from the cooperation between Romanian and Western firms has been increasing considerably.

The /orientation toward the developed free-market economies/ is reflected in a number of moves: the accession to the GATT Agreement and to the International Monetary Fund and the drawing closer to the European Community. In 1972, Romania--the first East European country prepared to recognize the EC--applied for preferential rates of duty, which were granted because Romania's developmental level was comparable to that of other developing countries. Romania also accepted the EC offer concerning conclusion of separate trade agreements with CEMA countries. In the spring of 1980, there was concluded a comprehensive agreement concerning trade and cooperation, including the establishment of a mixed committee.

One gains the impression that the restrictive negotiations between the EC and Romania have always been delayed by the EC, even though the EC has been appreciative of Romania's attitude--an attitude diverging from the position taken by the other CEMA countries. Concrete steps have always been put off, until international events (e.g. Afghanistan) made appear imperative concessions vis-a-vis Romania.

Since 1965, the Federal Republic of Germany has been Romania's most important Western trading partner. The FRG's willingness to extend the relations with Romania is evident from the fact that in regard to the level of credit surety, Romania is in second place--behind the Soviet Union--among the CEMA states. These supportive measures are necessary, since the imports of modern technology from the Federal Republic cannot be compensated by the Romanian exports of raw materials, semifinished goods or products of the food and textile industries. Since most of the Romanian exports to the EC area go to the Federal Republic (1978: 42 percent), it is safe to assume that in consequence of the agreement between Romania and the EC the Romanian efforts toward a reduction of the trade deficits vis-a-vis the Federal Republic will meet with success.

Romania feels that the economic relations can best be extended through /bilateral or trilateral cooperation/ in the production sector. At the end of 1979, the regulations--established in 1979--concerning the formation of mixed companies in Romania were improved by an "Agreement Concerning the Promotion and Mutual Protection of Capital Investments" between the Federal Republic and Romania. This "Investment Promotion Agreement" is the first agreement concluded by the Federal Republic with a state-trade country. It was learned that the /joint ventures/ have been granted a special status within the Romanian economy so as to support their activities. Nevertheless, there have been difficulties:

--The high rates required for setting up business restrict the circle of interested parties to large-scale enterprises;

--certain inflexibilities inherent in centralized economic control occasionally interfere with production, e.g. as a result of material shortages;

--the difficulties involved in the handling of two currencies.

On its part, Romania runs /mixed enterprises/ in /Western industrialized countries/, for the most part in the commercial sector, but also in the production sector (e.g. coal production enterprises in Canada and in the United States).

As regards /trilateral cooperation/, there are further possibilities that go beyond the present framework, since in the last few years Romania has been steadily extending its economic relations with the developing countries. Upon Romania's admission to the "Group of 77 Nations", the contacts with the developing countries have been intensifying. This process of rapprochement was promoted by Romania's foreign policy conception of dissociation from the blocs; at the same time, it was oriented toward the nonaligned countries.

Considering the general /prospects of cooperation between the Federal Republic of Germany and Romania/, one should first take note of the favorable political starting position. At the end of May 1980, the two countries

agreed to engage in regular consultations on international problems. In various fields, there exist possibilities concerning the development of economic cooperation. Thus there is the Romanian proposal concerning German participation in the Danube Canal Project. Proceeding from the assumption of a linkage of waterways from the North Sea to the Black Sea, one could readily conceive of German involvement in such a project. In this connection, one should point out that Romania is the only CEMA country that is prepared to recognize the Rhine-Main-Danube Canal as a German national waterway and to enter into a bilateral agreement concerning use of the canal. In view of the Romanian intention to develop a nuclear industry of its own, cooperation would be of interest in this field as well. There are other fields, e.g. electronics, machine building, and technologies for the recycling of raw materials.

Trilateral cooperation would be good policy in those developing countries that show greater reserve vis-a-vis the "Western world" than toward the smaller socialist countries. Romania has been remarkably successful in cultivating its relations with developing countries and has been accepted by them as an economic and political partner. In critical situations, cooperation involving Romanian enterprises could possibly be helpful in regard to maintenance or reestablishment of relations with developing countries. A good example in this respect is the Romanian position in Iran.

Considering the continuation of economic relations with Romania, one should also take into account the following circumstances. It is obvious that Romania--for reasons of economic and political independence--wants to extend its contacts outside the CEMA area. On the other hand, Romania's economic organization shows considerable shortcomings--even in comparison with other state-trade countries--and these shortcomings impede economic cooperation. Another factor mentioned is the Romanian leadership's "concern with prestige." In this respect, however, one should take into consideration that this concern with prestige is bound up with the Romanian leadership's desire for independence. In view of Romania's advocacy of political detente in Europe, the relatively low cost of cooperation with Romania should be brought in relation to other financial expenditures, e.g. to those that are required for the European armaments balance. Frequently, it is only after the emergence of an international crisis that assistance is lent to countries that have been in difficulties for some time. Good examples in this respect are the EC agreement with Yugoslavia or the financial aid to Turkey--even though it had been known for a long time that instabilities of these countries on the fringes of the great power blocs are intensified by economic difficulties. Such considerations probably apply to Romania as well--a country whose political position in the East European confederation of states is well-known. This argumentation derives support from the fact that other Western states, too, promote economic cooperation with Romania along these lines.

Possibilities Regarding Scientific Cooperation Between the Federal Republic of Germany and the Soviet Union

In the Final Act of the Conference on Security and Cooperation in Europe, the participant governments declared their intention to eliminate the obstacles to further improvement of the scientific-technological cooperation and to expand and improve within the framework of their jurisdiction scientific cooperation and exchange. To this end, they pointed to activities--ranging from loose contacts such as the exchange of information and publications to the formation of study groups concerned with common-interest topics in basic and applied research and with cooperation in research and development on the company level--that extend to nearly all forms of international scientific cooperation. The provisions of the CSCE Final Act show that at that time the governments had cherished relatively great hopes concerning the possibilities of scientific cooperation between the different systems. In the field of science and technology, the development of cooperation has been much less significant--in regard to both quantity and quality--than that in the economic sector.

The /greater reserve in scientific relations/ is understandable; for in the scientific cooperation between the systems, complications result from the fact that the divergent sociopolitical orientations permeate the scientific systems in East and West. Complications arise all the sooner, the more the subjects of cooperation extend from the scientific-technological realm into that of the social sciences. However, in evaluating these circumstances, one must take into consideration that results of the social sciences and humanities are generally less capable of international transmission, whereas the technical sciences are of a more universal character.

Consequently, the projects in the inter-systemic /scientific cooperation in the technological-scientific realm/ are less controversial than those in the humanities and social sciences. Moreover, in the scientific and technological disciplines, one encounters research problems that necessitate a greater input of material resources and that therefore suggest international cost and benefit sharing. Finally, scientific-technological cooperation would continue and complement the existing economic cooperation, with the exchange of technical knowledge on its part giving fresh impetus to the economic relations. Without the East's indisputable interest in the transfer of technology, the economic relations would not have reached their present dimensions. The conception of science as a "productive force" suggests similar motivations underlying the scientific contacts with the Western industrialized countries.

The /scientific-technological relations between the Federal Republic of Germany and the Soviet Union/ stay for the most part within the framework of the respective general East-West relations. So far, the relations in the scientific-technological realm have been marked by three distinguishing characteristics. Firstly, the relations are based on inter-company contacts: Only /one/ inter-state agreement, namely with Romania, has been

concluded in the field of scientific research and technological development. Secondly, the transfer of technology largely takes place from the West to the East. Thirdly, this transfer focuses on Eastern imports of capital goods. However, there is increasing emphasis--primarily in East Europe--on the utilization of other forms of technology transfer: purchase of licenses, inter-company cooperation in regard to technology-intensive products and inclusion of research and development in this cooperation. In the field of research and development, the Soviet Union engages in a special form of cooperation with Western enterprises: It promotes skeleton agreements between Western enterprises and the State Committee for Science and Technology (GKNT), the Soviet Union's principal decision-making and coordinating institution in the field of science and technology. In accordance with the given circumstances, these skeleton agreements must be concretized by specific projects. For the most part, they have resulted in exchanges of views among experts, and occasionally, in licensing agreements. Certain progress has been made in regard to research and development projects involving FRG enterprises. Thus cooperation on technical development--both with East Europe and with the Soviet Union--has not yet progressed past the initial stages.

An approximately equal developmental level of research and development among the partners facilitates the international scientific-technological cooperation. From the point of view of expenditures on research and development, the Soviet Union offers the most favorable conditions for progress in regard to research. Since the beginning of the 1960's, the Soviet Union has steadily been expanding its /scientific potential/. Both in regard to the absolute financial expenditures and in regard to the research and development share of the GNP, the Federal Republic of Germany clearly lags behind the Soviet Union. The number of scientists, engineers and technicians engaged in research and development is approximately 6 times as high as in the FRG.

However, the considerable expenditures on research and development are insufficiently utilized for foreign trade:

--The Soviet Union can boast of no more than approximately 10 percent of the FRG's issues of letters patent in foreign countries.

--Regarding its trade in patent licenses and research-intensive finished goods--both with the FRG and with other Western industrialized countries--the Soviet Union shows clearly negative balances.

Regarding this state of affairs, several explanations can be adduced:

--There is a lack of coordination between the research and development sector and the production enterprises.

--The enterprises are insufficiently motivated in regard to the introduction of new products and production methods.

--To some extent, the research and development sector is insufficiently equipped with scientific apparatus and equipment. Among other things, this is a result of faulty coordination between the research institutions and the producers of scientific apparatus.

--The generally low level of foreign trade activity makes itself felt in the foreign contacts maintained by the research and development sector.

On the basis of these explanations, it is safe to conclude that Soviet research has not been very successful in regard to the application of research and development results to prototypes and test installations or to new products and production methods. But these explanations also suggest that the Soviet Union's scientific and technological capacities are insufficiently developed for direct international exchange and that they are unevenly utilized, because in consequence of the fact that the research process is centrally controlled the research and development results are greatly dependent on administrative priorities.

Proceeding from the above assumption, one can expect the /Soviet Union to have reserves in the realm of applied research/--e.g. expertise concerning technological problems and their solution, patentable ideas, testing procedures, models of apparatus and instruments. Research areas suitable for international cooperation would be based on focal points of Soviet research policy. Thus, applied research has probably yielded a great many results in iron and general metallurgy, in welding technology, foundry technology, construction technology, mining technology and in the energy supply sector, and to a lesser extent, in electronics, automation, chemistry and in the consumer goods sector.

The selection of /research institutes/ presupposes more detailed information. For the most part, applied research is carried out in the research institutes of the branch ministries. In regard to the capacities of these institutes, it is difficult to generalize, since as a result of specialization there are considerable qualitative differences between the individual research institutes. There are probably some 100 institutes that are comparable to the leading institutes for industrial research in the Western countries.

While there is no doubt that there are /qualitative/ differences among the many /research institutes/ of the branch ministries (and among the applied research centers of the universities), the basic research institutes of the USSR Academy of Sciences (ANSSSR) must be regarded as excellent. Cooperation in basic research may develop in areas, where the research interests of the Federal Republic of Germany and of the Soviet Union are identical, e.g. energy and raw materials research, transportation and traffic technology, developmental and radiological protection, medical research, health- and nutrition-related technologies, urban and regional planning. However, certain projects, e.g. projects in energy-related basic research, cannot be implemented until the agreement on German-Soviet cooperation in the sciences

is ratified. Most of the above-mentioned fields are related to the economic-technological development potential. However, cooperative research appears to be promising in the social sciences as well, insofar as it pertains to social development in connection with technological development, e.g. to problems concerning present-day work or changes in the social structure.

For various reasons, /basic research/ offers /more favorable conditions for cooperation/ than does applied research:

--Rapid development of commercially useful technologies is not of overriding importance.

--In various basic research disciplines, progress depends on imaginative theories rather than on the supply of scientific apparatus and instruments.

--Soviet basic research has produced pioneering results by means of the concentration of financial and manpower resources that is a distinguishing characteristic of the planned economy. In the fields characterized by rapid development of scientific apparatus and instrument building, the results have been less impressive.

International cooperation in research and development is furthered not only by approximate equality in the partner countries' performance levels, but also by similarity in regard to the /organizational structure of research and development/. In the Federal Republic of Germany and in the Soviet Union, however, the research and development sectors are organized differently. In the Soviet Union, research is for the most part centrally planned and its implementation takes place within a complex organizational structure. This is true above all of applied research. Consequently, various decision-making, planning, and licensing agencies are involved in the international cooperation in applied research (generally the appropriate main administration of a branch ministry, the GKNT, the organization for material-technological supplies (GOSSNAB) and the appropriate foreign trade organization) and this necessitates considerable efforts in regard to communication and coordination. In basic research, these expenditures are not as great, but here the search for areas suitable for cooperation is impeded by communication difficulties.

As regards inter-systemic cooperation in research and development, the distinguishing characteristic is bureaucratic, not spontaneous or decentralized collaboration. It is only by the former approach that inter-systemic cooperation can be set going. However, in the course of development it would be necessary to complement the bureaucratic component by a reduction of formalized relations and by direct contacts among researchers or research institutions. In view of the East's interest in improved utilization of the benefits offered by cooperation in research and development, it is safe to assume that steps in this direction will be taken.

However, immediate drastic changes are not to be expected, nor should they be sought.

All-European Cooperation in the Energy Sector

I. Preliminary Remarks

Within the framework of the economic cooperation between East and West after 1970 and in the linking of the economic relations with the policy of detente, the energy sector has been playing an important and promising role--at least in the Soviet view. This became apparent as early as the 24th Party Congress (1971), but also in the Final Act of the Conference on Security and Cooperation in Europe (1975), in the proposal concerning the holding of an all-European energy conference, in the efforts on the ECE level and finally in the German-Soviet Economic Agreement of 6 May 1978 and the resultant Long-Term Program of 1 July 1980. The economic background and the political implications should be delineated so as to bring into focus the importance and prospects of the cooperation in the energy sector, especially with a view to the continuation of the CSCE process.

II. Background of East-West Cooperation in the Energy Sector

1. The Energy Situation in the Soviet Union and in East Europe

CEMA as an economic bloc produces over 100 percent of its own energy requirements, i.e. the region's energy exports exceed its imports. In 1978, production exceeded consumption by 15 percent. But practically it is only the Soviet Union and, to a lesser extent, Poland that benefit from this production surplus. All the other CEMA countries are deficit regions that satisfy their energy requirements primarily through imports from the Soviet Union.

Since the Soviet Union accounts for 79 percent of CEMA's energy production and for 71 percent of its energy consumption,[1] we will first describe the energy situation in the Soviet Union. In the 1970's, the Soviet Union developed into the world's biggest oil producer, and among the leading industrialized countries, it is the only country boasting an energy surplus. Nevertheless, there are indications of potential problems in that production is no longer sufficient to meet the diverse demand.

Table 1 shows that since 1974 energy production has been characterized by steadily declining growth rates. During these years, however, the production increases still exceeded the increase in consumption; consequently, the net export share of production increased from 18 to 22 percent. Comparing the rise in energy consumption and overall economic growth, one realizes that an uncoupling of the two growth rates to the extent practiced in the Western industrialized countries was not feasible. Between 1973 and 1978, the rise in energy consumption was somewhat lower than the increase in national income as indicated by Soviet statistics (relation 0.9).

However, in order to be able to produce comparable data, one has to convert the national income into the GNP variable used in the West. On the basis of the pertinent CIA figures, the relation between the rise in energy consumption and economic growth is 1.2, while the comparative figure for the FRG was 0.3 between 1973 and 1978 (rising considerably after 1979, however). As regards the 1980's, neither the development in the 1970's nor the pertinent prognoses offered by experts—including a Soviet observer (Mel'nikov)--justify the assumption that this relation in the Soviet Union will drop below 1.[1a] This means that Soviet economic growth is limited by the rise in energy consumption. The rise in consumption on its part is determined by the production increases and the changes in exports and imports so that in the event of a continuing decline in the production growth rates continuous consumption increases can be maintained only through a curtailment of exports.

Table 1. Increase in Soviet Energy Production and Consumption, 1973-1979 (%)

	1) Produktion				6) Verbrauch
	2) Öl	3) Gas	4) Kohle	5) Energie	Energie
1973	7,1	6,7	1,9	4,9	5,6
1974	7,0	10,3	2,5	5,6	4,2
1975	7,0	11,0	2,5	5,2	5,7
1976	5,9	11,0	1,5	5,0	4,8
1977	5,0	7,8	1,5	4,7	3,3
1978	4,7	7,6	0,2	4,1	3,1
1979	2,5	9,4	-0,7	3,3	1,8*

A further drop in production is likely, since it will be practically impossible to influence the cause of the decline in the growth rates, namely the rise in investment costs accompanied by an insignificant expansion of capital goods.

With the exception of natural gas, which in 1979 accounted for 25 percent of total energy production, the production targets have not nearly been met. As regards coal (26 percent of total energy production), the 1979 production volume was clearly below that of the two preceding years, while the growth rate for oil (45 percent) amounted to a mere 2.5 percent. Only

in the production of natural gas are the growth rates as high as planned; it should be pointed out, however, that the 1980 plan provides for lower rates.

The other primary sources of energy, above all water-power and nuclear energy, presently account for less than 5 percent of total energy production and they are not likely—neither in the short or in the long term--to improve the energy balance. According to estimates of the ECE, in 1990 nuclear energy will account for 2 percent, and water-power for 3.3 percent of the Soviet Union's total energy production.[2]

The energy production picture will give rise to concern, if the CIA oil production prognosis that was first published in 1977[3] and that has since been repeated with minor changes will come true before 1985. In contrast to the prognoses of other institutes, the CIA data proved to be very accurate for the first 3 years, which allowed comparison of the prognosis and the actual results; consequently, a large number of well-known experts expect the CIA prognosis to be accurate in regard to the coming years as well.[4] Likewise, a well-known Soviet energy expert, A. Krylov, holds that unless there are technological innovations, production will culminate in the near future and then decline.[5] According to the CIA prognosis, after 1980 production will by 1985 drop to the production level of 1975. Exports to the East European countries will rise only slightly. In 1981, the net exports to the West will be discontinued, and in the following years, Soviet demand in the OPEC markets will exceed by up to 100 million tons the exports to the Western countries. According to a subsequent CIA projection,[6] the Soviet Union will to some extent be able financially to compensate the oil imports through increasing natural gas exports; however, the natural gas exports will then restrict the possibilities of shifting domestic energy consumption from oil and coal to gas.

Due to the fact that coal accounts for a large share of energy consumption, the self-sufficiency rate of the East European countries is as high as 79 percent; however, of the total energy imports, oil accounts for 69 percent, and oil imports from the Soviet Union, for 53 percent. Energy imports from outside the CEMA account for only 16 percent of total imports and for only 5 percent of the energy supplies as a whole.[7] The trend toward a disproportionate rise in the share of imports from the countries outside CEMA was almost completely undone by the international price hikes.

In the East European countries, the import requirements as an expression of the difference between consumption and production are most clearly reflected in oil. While consumption in these countries amounts to 100 million tons, domestic production totals 18 million tons. Disregarding Romania, whose oil imports from the Soviet Union have so far been negligible, consumption amounts to 77 million tons, while production totaled barely 3 million tons. In view of the financial situation of the East European countries, the demand must be covered almost in its entirety by the Soviet Union, and this demand is increasing disproportionately, since

these countries--inclusive of Romania--cannot expand their production any further and since in consequence of the industrialization process they are increasingly dependent on oil, a flexible energy source.

As regards natural gas, the situation is similar. Here the Soviet Union meets nearly the entire import requirements of the East European countries. As regards coal, however, the Soviet exports are not as significant. In this sector, it is above all Poland that satisfies the relatively limited requirements of the East European countries.

2. The Soviet Efforts Toward East-West Cooperation

Since 1971, the Soviet Union has been making diverse high-level efforts aimed at solving the energy problems through cooperation with the West or broaching the energy problem as a problem concerning all European countries. At that time, the Soviet Union was in a position to perceive with greater farsightedness the problems pertaining to the supply of energy, since the energy supply could largely be determined by its own economic parameters and--more importantly--since the supply was not affected by international political conflicts.

The parallel development of detente notwithstanding, the expectations concerning cooperation with the West exceeded the actual possibilities of implementation. Thus the Soviet Union hoped to be able--with Western financial aid--by 1990 to meet 16 percent of its energy requirements through capital-intensive nuclear power.[8] According to present prognoses for 1990, 3 percent will be the maximum attainable. To some extent, the--in the Soviet view--unsatisfactory development of cooperation is rooted in the problems involved in inter-systemic economic relations, in the trade imbalance, in the inefficient capital utilization in the Soviet Union, etc. The Western countries' hesitation in the political realm is another factor.

The Final Act of the Conference on Security and Cooperation in Europe attached great importance to cooperation in the energy sector, considering it a contribution to long-term, stable relations;[9] in December 1975, a few months after the Helsinki Conference, there followed Brezhnev's proposal concerning the convening of a European energy conference based on the CSCE. As time went by, the hesitant response of the West gave rise to growing disappointment in the Soviet Union.

In view of the conditions prevailing at the Belgrade CSCE successor conference (1977/78), it was impossible to transform into a resolution the willingness--signaled above all by the FRG--to take certain steps in this direction.[10] It was not until the annual ECE conference in April 1979 that there was established a body of "Senior Advisers to ECE Governments on Energy" that is to assist in the process of working out a resolution concerning the holding of an all-European energy conference.

3. The Cooperation in the Energy Sector in the 1970's

The stagnation of cooperation in the energy sector is by no means attributable to the fact that so far the Soviet proposals concerning an energy conference have not been implemented. Rather, it is precisely in this sector that significant agreements have been concluded, above all the agreements concerning the delivery of pipes that were financed through loans, repayment of which was to take place in the form of long-term natural gas shipments. It is through oil shipments--more so than through the shipments of natural gas--that the Soviet Union obtains the foreign currency needed for covering its import costs. In the last few years, the Soviet Union obtained through oil and natural gas exports 50 to 61 percent (1978) of its foreign currency revenue from Western industrialized states. Likewise, imports of equipment for the development of energy resources have assumed increasing importance for the Soviet Union.

One should also mention the fact that Poland has been obtaining approximately one-third of its foreign currency revenue from coal exports and that it has expressed interest in intensive cooperation with Western enterprises in the field of coal refinement.

Nevertheless, it is obvious that the demand for Western technology and Western capital has not nearly been met--technology and capital needed for projects such as development of the large oil fields in the Barents Sea or of the Yakutsk gas deposits. However, it is not only since the Afghanistan crisis that the United States has been pursuing a restrictive policy in regard to the issue of making accessible to the Soviet Union technologies for resource development. The West European enterprises on their part considered certain offers insufficiently concrete, or the negotiations remained inconclusive, as was the case in regard to the project involving establishment of a nuclear power plant near Koenigsberg (Kaliningrad).

III. Dependence and Interdependence Through Cooperation in the Energy Sector

1. Dependence of the West

At present, Western Europe satisfies 6.6 percent of its energy requirements through imports from the CEMA countries. Although this percentage is not negligible, it is certainly not high enough to generate dangerous pressure in regard to security policy. This possibility exists only in Finland and Austria; while their energy dependence on the Soviet Union and Poland is disproportionately greater, these two countries import correspondingly smaller contingents from the OPEC countries. For the EC, this energy dependence on CEMA amounts to 4.9 percent, and for the FRG, to 4.2 percent.

Considering domestic consumption, the FRG's dependence on the Soviet Union is most pronounced in regard to natural gas (15 percent); as regards oil (3 percent) and coal (2 percent), on the other hand, the dependence is

insignificant. However, the dependence in regard to natural gas is not so critical, since the FRG can meet 80 percent of its requirements through domestic production and through imports from Norway and the Netherlands, i.e. secure sources. Moreover, the gas supply companies and the industrial customers have concluded agreements, according to which the customers are obliged--in the event of a shortage--to switch over to other energy sources (oil, coal).

Even in the event of massive financial aid to the Soviet Union, it is unlikely that the oil share of the Soviet exports to the West European consumers can be raised again, but in regard to gas (and also coal (Poland), the domestic supply of which exceeds that of natural gas), the shares could possibly be further increased, if closer cooperation in the energy sector were instituted. In regard to natural gas, however, the Soviet Union is presently confronted with compensation problems due to the discontinuation of the planned imports from Iran.

In considering dependence, one should also compare the alternatives. As regards oil and natural gas, the imports from the Soviet Union could at best be replaced by imports from the OPEC countries, for the West European resources are fully utilized anyway.

2. Dependence of the East

It is more difficult to quantify the CEMA countries' dependence on East-West cooperation, since it is hard to determine to what extent improvements in energy production and energy transport are attributable to the Western equipment shipments. Nearly the entire imports of pipes for pipelines come from Western industrialized countries and the imports of Western equipment for the development of energy resources have increased considerably. If one considers the orders of this type of equipment to be indicative of future purchases,[11] a further rise in demand is to be expected, unless energy production falls short of the plans and domestic growth requirements to an even greater extent than is obvious even now. In view of the decline in oil production in the European part of the Soviet Union and in view of the stagnation in the West Siberian oil fields, in the coal production sector and in the overall energy production of the East European countries (with the exception of Polish coal), it is imperative that new energy sources be opened up in regions that are more remote from the consumption and distribution centers--regions that thus necessitate infrastructure-related transport measures and that due to the extreme geological and climatic conditions require heavy input in regard to technology. For these tasks, Western equipment is needed more urgently than ever.[12]

With the exception of Romania, the East European countries will be totally dependent on the oil and gas imports from the Soviet Union. In view of their indebtedness, their financial situation is much more critical than that of the Soviet Union; consequently, it is difficult for them to pay for additional energy supplies with foreign currency. Under no circumstances

would they be able to compensate a decline in the Soviet shipments through imports from the OPEC countries.

3. Interdependence as an Element of Detente

Aside from the economic realm, interdependence could stabilize the relations between the partners. However, this would require certain structural factors. Thus the dependence of certain OPEC countries on Japanese capital goods can hardly be considered a stabilizing compensating factor vis-a-vis the Japanese dependence on energy imports from the OPEC states. In particular, a short-term dependence on vital commodities cannot be compensated by any long-term dependence.[13]

In regard to East-West relations, the view that stable economic interdependence can be considered a significant contribution to detente was reflected above all in the Final Act of the Conference on Security and Cooperation in Europe. In regard to the stabilization of the relations, this document proposes a number of measures (avoidance of abrupt fluctuations in merchandise traffic, diversification, exchange of information, etc.) and in regard to protective measures ("permanent ties"), it suggests various forms of cooperation on diverse levels, including cooperation in the energy sector.

In contrast to the European governments in the East and the West, the United States has never made this approach concerning an independent contribution of the economic relations to detente an integral part of their own policy: Even after 1970, the economic relations with the Soviet Union were to be extended only in return for conduct promoting detente. This goes for the Jackson/Vanik and Stevenson amendments (1974) as well as for the basic principles of the policy of detente as formulated by Kissinger[14] or Carter.[15]

The West European countries, and the FRG in particular, had proceeded from the assumption that a basic framework was to be established for the policy of detente, in the maintenance of which both sides would take an interest and which was to counteract any conflict extensions. The economic relations appear to be a suitable means to this effect. In his London speech of 1977, Federal Chancellor Schmidt expressed this in the following words: "(One of the) major tasks of Western security policy in economic terms is to establish balanced and stable economic relations with the communist state trading countries of the East."[16] In this regard, the German-Soviet Economic Agreement of May 1978,[17] which is intended to extend over 25 years and which documents the close link between economic relations and the policy of detente, has reference not only to the Final Act of the Helsinki Conference, but also to a 20-year-old bilateral treaty policy.

The West European countries' efforts to establish long-term, stable interdependence in the economic sector, in which they can develop parity-based relations with the Soviet Union and the East European states, certainly

could be a security policy-related complement of the attempts--supported primarily by the United States--to establish a balance of power based on military factors.

4. The Problems in Connection With the Embargo Policy

Economic relations cannot be developed independently of the political environment. In the first half of the 1970's, the East-West economic relations in particular underwent an intensification that was closely related and parallel to the process of detente. Thus it seems only natural that the disillusionment that became apparent in the policy of detente after the invasion of Afghanistan extends to the economic relations as well. However, an embargo in regard to the cooperation in the energy sector, in particular in regard to the shipments of equipment, would signify total abandonment of the objectives formulated in the Final Act, for in the Final Act it is precisely the energy sector that is singled out as a field suitable for long-term, stable cooperation, since measures concerning the exploration, exploitation and transportation of energy resources necessitate long-term planning.

The objective of long-term cooperation formulated in the Final Act was not bound up with the hope that there would no longer be any East-West crises. Rather, the participants were fully aware of the fact that a stabilization of the relations in Europe would not by any means rule out the possibility of a continuation of the East-West conflict in the Third World. If the Soviet Union forcibly initiated changes in the Third World and if these changes necessitated countermeasures by the West, the measures contemplated should be chosen with great care so as to rule out any destabilizing effects in Europe.

5. The Global Responsibility

In the light of prognoses submitted by the most diverse institutions such as the International Energy Agency, the Club of Rome and economic institutes, it seems safe to assume that in the 1980's the struggle for the largest possible shares of energy and raw materials will be intensifying. At the same time, the Soviet Union is likely to enter the international markets as a buyer or--if it lacks the financial means necessary--to seek other ways of sharing in the available energy resources, namely by fanning existing conflicts so as to create options for obtaining raw materials. In order to avoid creating--in addition to the potential conflicts in the Third World--an East-West conflict over the distribution of raw materials, the Western industrialized states must see to it that the Soviet Union can exploit the reserves on its own territory--thus increasing, if possible, the supply in the world market--and, as the ultimate objective, that the Soviet Union share in the global responsibility concerning raw material supplies. Naturally, this does not mean that the Soviet Union should be granted additional control over the exploitation and distribution of raw materials--which is one of the interpretations given the proposal by

Portugalov concerning a joint safeguarding of the transport routes in the Persian Gulf;[18] however, it could be interesting on the basis of precisely this proposal to discuss the Soviet conceptions concerning steady raw material supplies in the coming decades. It is difficult to imagine that this increasingly urgent discussion could lead to stable results without the participation of the Soviet Union--a country that on the one hand has at its disposal the most abundant raw material deposits and the largest natural gas and coal reserves and that on the other hand could take advantage of crisis situations, above all crisis situations in the Near East. On account of its great potential in regard to capital and technology and its disproportionately stronger economic commitment in the Third World, the West's position vis-a-vis the Soviet Union would by no means be unfavorable in such a discussion.

IV. The Future Cooperation

1. Projects for the 1980's

Provided that it is possible to come to a political decision in favor of intensified cooperation, one might consider--in accordance with considerations circulated within the ECE--the following projects:

(1) Tapping of the oil reserves in the Barents Sea. The largest untapped oil reserves of the Soviet Union are located in this Arctic region, where Western technology--based on the experience gained in Alaska and in the off-shore work in the North Sea--is far ahead of the Soviet technological capacities. Another problem is the Soviet Union's lack of investment capital for the creation of transport capacities.

(2) Coal refinement in Siberia. Coal-refinement procedures (gasification, liquifaction) developed in the FRG and in the United States could be put to especially good use in the Soviet Union. The conditions are favorable, because in Siberia there still are largely untapped coal deposits (above all the Kansk-Akhinsk Basin), which for the most part can be exploited by surface mining, i.e. at low cost, but which for lack of transport capacities cannot be moved, or only at a cost far exceeding that of production. An on-the-spot refinement of the coal would allow transportation by pipeline at a fraction of the coal transportation costs; moreover, it would create a more flexible energy source and thus increase the supply of oil and gas--energy sources that are in relatively shorter supply.

(3) Coal refinement in Poland. An agreement cor ning production of just under 1 billion cubic meters of fuel gas per year--beginning in 1984 near Kattowitz--was concluded in February 1980 with the Krupp-Koppers GmbH.[20] Upon solution of the financing problem, further agreements in this field are probably desirable.

(4) Natural gas, the only energy source--aside from nuclear power--in regard to which the Soviet Union can hope--on the basis of its own

investments--to achieve production increases, necessitates additional transport capacities. Another pipeline linking the Soviet Union--via Polish and GDR territory--with the West European network in the FRG would be welcomed by the transit countries as well, since they hope to obtain a certain quantity of natural gas in the form of "transit fees." As regards the projects involving the delivery of pipes in return for natural gas, the East-West relations benefit from many years of experience.

(5) The East has repeatedly proposed what it considers a promising project--to link up the East European with the West European electric power network. Certain progress has been made in the discussions concerning the establishment of power-line links at both the Hungarian-Austrian and the Czechoslovak-Austrian borders. A similar link could be established between the FRG and the GDR, what with the FRG's concern with insuring a steady power supply for Berlin. Generally speaking, such links could serve to equalize conditions during peak load periods; on the other hand, unilateral boosts of the Western network by Eastern power plants are conceivable as well.

Such projects can be implemented only on the basis of long-term financing assurance and this means above all state guarantees by the Western countries such as are provided by the German-Soviet Economic Agreement of May 1978 and the supplementary stipulations of the Agreement of 1 July 1980. This implies extensive advance financing by the parties supplying most of the investment funds. Although this may be considered an unbalanced cooperation, it is a quite normal procedure in other regions, both within the Western industrialized countries and in their relations with the Third World countries. Whether the Western industrialized countries still can find more secure regions for their investments is open to doubt. At the same time, however, the Western countries could justly insist on political guarantees by the East concerning efficient utilization of the capital and on the Western investors' right of codetermination in regard to management decisions. In order to overcome the structural and political difficulties involved here, the Soviet Union will have to hold a high-level conference covering a broad range of topics.

2. Procedural Aspects

The committee of "Senior Advisers to ECE Governments on Energy", which was established at the annual ECE conference in April 1979 and which is to discuss the problems in connection with a high-level all-European conference on energy questions, has so far convened twice (October/November 1979 and March 1980). During the first round, the participating governments were asked to fill out a questionnaire concerning the future development of their countries' energy sectors.

The CEMA countries did not follow this agreed-upon procedure to the extent required. In justification, the Soviet Union pointed out that for the

years 1990 and 2000 accurate data concerning the production and consumption of the individual energy sources were unavailable. Realistically, the Western countries could not expect the Soviet Union completely to fill out this questionnaire. However, on account of the general cooling of the atmosphere in 1980, this information ramification was used in the subsequent ECE discussions as grounds for halting the negotiating process; consequently, the Madrid Conference will lack a proposal concerning the staging and the subjects of a high-level energy conference. If both sides are willing to intensify their cooperation, such a conference could still be authorized, provided there is an opportunity in Madrid for detailed, pertinent discussions.

The Development of Transportation in CEMA--Considerations Concerning All-European Cooperation in the Transportation Sector

The economic growth in the Soviet Union and in the states of East and Southeast Europe, which has been continuing for decades and which has been slowing only in the last few years, has led to a sharp rise in the demand for transport services in all sectors. With the expansion of foreign trade, the traffic flow has been intensifying, both in regard to traffic within CEMA and in regard to the traffic between the CEMA countries and the countries of the Third World. Insofar as it is becoming apparent that the available capacity reserves are fully tapped, the present deficiencies are making themselves felt even more strongly. In varying degree, this is the case in all CEMA countries and it is reflected in a large number of publications and official documents. In this regard, one should mention the resolution "Concerning Measures for Improving the Construction, Repair and Maintenance of the Country's Highways" (reprinted in EKONOMICHESKAYA GAZETA, No 18, 1980, p 2), which was adopted at the end of April 1980 by the CPSU Central Committee and the USSR Council of Ministers; the resolution clearly expresses the problems at hand and draws attention to the critical situation in regard to highway construction and motor transport--sectors that do not meet the requirements of the national economy.

In order to prevent the transport system's shortcomings from affecting economic growth, it will be necessary to allocate to the individual carriers a larger share of the investments. But even if this were done, the CEMA states would hardly (if at all) be able to carry out the necessary modernization and expansion of their transportation systems.

In view of these conditions, the question is whether the transportation sector might offer new possibilities concerning economic cooperation along the lines of East-West cooperation suggested by the CSCE Final Act. In view of the transport situation in the CEMA countries, one may safely assume that the Eastern side is interested in such cooperation, at least in certain areas--as long as such cooperation does not provide information on armaments-related sectors.

The present study arrives at the following statements and conclusions:

In regard to /performance/, all of the carriers are insufficient. The shortcomings manifest themselves in various areas:

--In insufficient capacity;
--in the obsolescence of the transport facilities and the resultant deficiencies in the technical equipment;
--in the insufficient mechanization of the loading and unloading operations and in the resultant shortcomings concerning labor productivity and the handling of the transport containers;
--in the lack of spare parts that of necessity leads to stoppages and thus to a shortage of cargo space;
--in the shortage of specialized cargo space;
--in faulty work organization;
--in the hitherto insufficient utilization of the possibilities offered by electronic data processing and the resultant rationalization possibilities.

In the past decades, the CEMA states made considerable investments in their transportation systems. In so doing, they concentrated on key projects and it appears that these investments were preceded by consultations within the CEMA framework. Nevertheless, there still are considerable shortcomings in this area.

With the exception of the Soviet Union, the CEMA countries have not expanded their national /railroad/ networks--even though these networks are generally not distinguished by a high degree of coverage; some of the CEMA countries even curtailed the railroad network.

However, the transport volume and transport efficiency have been increasing considerably, a fact attributable--among other things--to electrification and introduction of diesel engines on the principal routes. But due to the inferior quality of the track bedding, the trains cannot travel at full speed. Thus in this area there still are untapped reserves.

A focal point in the expansion of the transportation sector are the /pipelines/, without which transportation between the USSR and the CEMA states would have been severely impeded. In 1978, the "Friendship" pipeline alone conveyed over 500 million tons of oil.

As regards /maritime transportation/, the CEMA states have been expanding their merchant fleets so as to save or obtain foreign currency. This expansion was accompanied by an extension of the port capacities; nevertheless, as regards the technical equipment of the ports, the shortcomings are still quite extensive.

In most of the CEMA states, /road transportation/ plays only a minor role, largely because of neglect or because of the poor road conditions. However,

trucks, repair centers and other infrastructure facilities are likewise in short supply.

/Air traffic/ is of importance above all in the USSR, where it is the primary mode of cargo transportation, especially in the developing regions. In the past few years, the air fleets of the CEMA countries have been expanded; they are made up almost exclusively of Soviet planes. Within the framework of the CEMA countries' long-term transportation program, a number of airports are being constructed or modernized. Electronic booking systems are to be introduced.

In comparison with the other carriers, /inland navigation/ plays only a minor role in the CEMA countries. The USSR is an exception in this regard; in this country, however, the use of inland ships is restricted by the climate, by the direction of the principal rivers and by the insufficient number and equipment of the inland ports and moorages.

On account of the increasing economic interdependence of the CEMA states and the resultant commodity exchange, the CEMA organs have for a number of years been directing special attention to the /joint development of the transportation systems/. The "Long-Term Target Program" (LZP) that was expressly developed for the transportation sector is to provide the foundation for the joint transportation policy. Essentially, it is five factors that are to determine the development of transportation within CEMA in the coming years:

—Intensification of the commodity exchange within the framework of economic integration;
—the requirements resulting from the increasing trade with third countries;
—economic growth and (in the USSR) regional development;
—establishment of large-scale industrial projects—partly intended to supply CEMA as a whole—entailing high-density effects resulting in strain on the transportation system;
—the increasing production specialization within CEMA, which entails new qualitative and quantitative demands on the transportation systems of the member states.

Since the railroads account for approximately 50 percent of intra-CEMA traffic, they are the principal target of the integration measures. In this respect, a number of measures have been taken—in regard to transport regulations, rates, and above all in regard to the modernization of the railroads and the establishment of a "Uniform Container Transport System"—that are intended to improve the overall situation. The laying of Soviet-gauge track linking the USSR with Romania, the CSSR and Poland naturally is of military significance as well. Likewise, in the realm of maritime navigation, the second most important means of transportation within CEMA, various agreements have been concluded and implemented that serve to expand the cooperation. However, in this field, too, it has not been possible to solve all of the acute problems.

A special problem in regard to intra-CEMA transportation [illegible] the rise in the average transportation distances, which entails increas[illegible] ansport costs for the participant countries. So far, none of the mea[illegible] intended to counteract this development have produced the results de[illegible]

Generally speaking, one can say that the /integration in the transportation sector/ is proceeding along the following lines:

--Via joint planning and plan coordination;
--via joint international CEMA organizations;
--via joint ventures in the transportation sector;
--via specialization agreements;
--via pooling agreements;
--via joint agreements on rates.

The /Long-Term Target Program concerning cooperation in the transportation sector/ comprises a catalog of tasks and measures, implementation of which is regarded as especially urgent:

--In accordance with its general importance, rail transport occupies first place among the fields enumerated. Its efficiency is to be improved above all by increasing the traffic flow on all routes and through coordination of all technical elements.

--In regard to maritime and inland navigation, it is planned to improve the international cooperation of the shipping firms, to expand the repair capacities and to intensify transportation on the Danube.

--In regard to motor transport and highway construction, it is planned to develop organizational forms of cooperation, with special emphasis being placed on insuring a sufficient supply of spare parts. As regards air transport, the objectives are similar. The program does not discuss at any great length transportation by pipeline.

The concrete LZP measures concerning the individual carriers and individual transport connections include the expansion or construction of a number of international railroad lines and international highways, all of which are specified in the program. Of special interest are the measures that are planned in the field of inland navigation and that indicate that the CEMA states on the Danube are looking forward to the completion of the inland waterway from the Danube to the ports in the Rhine estuary and that these states are planning joint operations on this big waterway.

/Cooperation with the West European industrialized states/ could help solve the acute problems in the transportation sector of the CEMA countries. Such cooperation appears to be feasible in three areas:

--In the field of transportation technology through delivery of the modern equipment required;

--in the field of scientific-technological cooperation through transmission of the latest research results and of the practical experience gained in the establishment of transport routes;

--through direct and indirect financial aid.

Large-scale cooperation between the states of the European Community and the CEMA states in regard to the development of an all-European traffic network by means of joint planning and joint financing appears to be more promising than the above-mentioned partial cooperation, since it would help both sides to extend the merchandise traffic and to reduce the transportation costs. In this respect, one should consider expanding the principal West-East and North-South railroad lines and motor transport routes. The LPZ expressly provides for a link-up of the Eastern transport routes with those of the neighboring countries.

However, there are some other problems in regard to all-European cooperation in the transportation sector. Directly or indirectly, investments in the transportation sector are of military significance as well. The assistance lent in the expansion of the Eastern transportation systems also served to improve the strategic position of the Warsaw Pact states in the event of conflict. Consequently, even the cooperation in the transportation sector presupposes a certain degree of mutual trust within the framework of the general East-West relations.

Moreover, in engaging in cooperation in this sector, one must take into consideration the /Eastern pricing practices/ in regard to maritime and air transportation and in regard to navigation on the Danube. The latter should be evaluated above all with a view to the completion of the Rhine-Main-Danube Canal. Thus, prior to any discussion of cooperation projects, it would be good policy (especially in regard to the entry into the Central-European waterway network) to develop Western counterstrategies. In the event of cooperation in the transportation sector, it would be advisable to ensure through contractual arrangements that the Eastern side observe the rules of conduct prevailing in the West European markets.

12. Due to the oil price hike, the Soviet Union can significantly improve its trade balance. At best, however, the Soviet Union thus could offset the discontinued energy exports to the West, but it could not effect any large-scale purchases of energy. At a price of $600 per ounce and with sales totaling 400 tons (this volume was attained in 1977 and 1978, whereas the 1979 volume was much lower), the Soviet Union would take in $7.7 billion--an amount approximately equivalent to the proceeds from the 1978 oil and gas exports to the West.

CEMA CONFEREES DISCUSS AUTOMATIZATION OF GOVERNMENT PLANS

Moscow PLANOVOYE KHOZYAYSTVO in Russian No 10, Oct 80 pp 124-125

[Article by V. Nikitin and Ya. Urinson: "Conference of Experts on Questions of the Construction and Application of Automated Systems of Planning Calculations of Governmental Planning Bodies of CEMA Member Nations"]

[Text] The Conference of Experts on the Questions of Construction and Application of Automated Systems for Planning Calculations of the Governmental Planning Bodies of the CEMA Member Nations took place in April 1980 in Tashkent within the purview of the CEMA Committee on Cooperation in the Field of Planning Activities.

Taking part in it were delegations headed by N. Naydenovyy (People's Republic of Bulgaria, deputy chairman for the State Planning Committee); A. Vagi (Hungarian People's Republic, department head of the Institute for Economic Planning); G. Fayka (GDR, department head of the State Planning Commission); Kh. Barrera (Republic of Cuba, director of the Computer Technology Administration of the Central Planning Council); U. Bolde-Erdene (Mongolian People's Republic, department head of the State Planning Commission); Ya. Kramarchuk (Polish People's Republic, general director of the Government Computer Center for the Planning Commission of the Soviet of Ministers); Kh. Menesku (Socialist Republic of Rumania, director of the Electronic Computer Center of the State Planning Committee); N. P. Lebedinskiy (USSR, department chairman of the State Planning Commission, USSR); L. Krzhemechek (CSSR, director of the Computer Technology Institute of the State Planning Commission) and the chairman of the CEMA Secretariat, Yu. V. Borodin.

N. P. Lebedinskiy opened the conference. He stressed the great significance which is given in our country to the questions of the practical use of electronic computer technology and economic-mathematical methods in the improvement of planning, and also noted that the accumulated experience of the cooperation of the planning bodies of the CEMA member nations in the field of development of automated planning systems attests to the mutual benefit of the present bilateral relations. N. P. Lebedinskiy expressed conviction that the further development of cooperation in this field on a multilateral basis will facilitate the successful resolution of the planning modernization tasks facing our countries.

K. A. Akhmedov, deputy chairman of the Soviet of Ministers and chairman of the State Planning Commission of the Uzbek SSR greeted the conference participants.

In plenary meetings, the conference participants exchanged information on the state, the problems and the prospects for the building of automated planning calculation systems for the state planning bodies of the CEMA member nations. With consideration of the expressed opinions, the editorial group formed by the conference (the chairman is the first deputy assistant to the head of the Main Computer Center of the State Planning Commission USSR, V. B. Bezrukov), prepared and approved the following: generalized material on "Methods for Construction and Experience in the Use of Automated Planning Calculation Systems of the Governmental Planning Bodies of the CEMA Member Nations"; proposals for a program for the exchange of experience in the cited field for the period from 1982 to 1984 and a draft resolution of these questions for the upcoming 11th Conference of the Assistants to the Chairmen of the Central Planning Bodies and other responsible figures, who are in charge of questions on the improvement of planning and management systems of the economies of the CEMA member nations.

The generalized material notes that in the planning bodies of the CEMA member nations, great attention is given to the development and application of economic-mathematical methods and electronic computer technology for purposes of planning modernization. The works in the CEMA member nations in this field are identical in their initial theses and final goals. Thus, the necessity for the complex solution of the problem of automating planning with consideration of its methodological, informational, mathematical, technological and other aspects and the expedience of sequential introduction of the methods and means being developed for information processing into the practice of planning, both for resolution of traditional, as well as basically new economic planning problems, are generally recognized. In this, the basic goals of planning process automation lie in an increase in the balance and the operability of planning calculations, more complete coordination of the indicators of various sectors of the state plan, the provision of multiple variance of the basis and optimization of the planning decisions, improvement in the follow-up for plan fulfillment and the development of a planning information base.

Within these general theses, two approaches to their implementation may be isolated. The first is oriented towards the systemic application of economic-mathematical methods and electronic computer technology in planning and contemplates the development of a general concept for the construction of automated systems of planning calculations, whose stage by stage realization provides a sequential improvement in the planning practice. In this case, the design and introduction of automated systems into the work of the planning bodies are being conducted according to a common long-range plan, parallel to all of its supporting subsystems and functional assignments in conditions of a clearly determined organizational structure. The second approach gives preference to local automation of planning calculations and independent development of separate software. The central planning bodies of the CEMA member nations, who support this approach, are basically developing short-term programs for the automation of planning calculations in order to solve the next urgent problems.

It is indicated in the generalized material being considered that the economic-mathematical models being developed and used in the central planning bodies of the CEMA member nations are designed, chiefly, for medium and long-range planning calculations. Modeling methods in the annual planning mode are used in the planning bodies of the GDR, the Polish People's Republic and the USSR.

Interindustry balance of payments, industry and complex optimizational, economic, as well as simple regressive models, have received the greatest dissemination.

Cost and real-cost interindustry balance of payments models are composed by the planning bodies of a majority of the CEMA member nations and are used basically for justification of control figures for the last year of the long-range plan. Dynamic interindustry models are used by the specialists of the planning bodies of the People's Republic of Bulgaria, the Hungarian People's Republic, the Socialist Republic of Rumania and the USSR at the national economic level and in the People's Republic of Bulgaria, the Polish People's Republic, the Socialist Republic of Rumania and the USSR at the industry level as well, and in the Socialist Republic of Rumania, at the level of individual objects of capital construction. An optimizational model for the development and distribution of agriculture is prepared in the State Planning Commission of the Mongolian People's Republic.

The econometric models being created in a number of CEMA member nations are used in the planning bodies, either as an instrument of so-called passive prediction, or in an imitational mode.

The simplest regressive models, especially trend models, find use for the prediction of individual indicators in the planning bodies of the Hungarian People's Republic, the GDR, the Polish People's Republic, the Socialist Republic of Rumania and the CSSR.

In the general opinion of the experts, the economic-mathematical models are used most widely in the activity of the planning bodies of the Hungarian People's Republic, the Polish People's Republic and the USSR. There are also extensive works in these countries and in the CSSR for the formation of systems of economic-mathematical models.

The generalized material gives the characteristics of the universal system software available in the planning bodies of the CEMA member nations. It is noted, in particular, that the pool of electronic computers consists basically, of third generation electronic computers with a capacity in their operational storage devices of no less than 512 kilobytes and magnetic disk storage devices with varying capacity (from 7.25 to 100 megabytes). Moreover, minicomputers are widely used in a number of countries. In the majority of the computer centers of the planning bodies of the CEMA member nations, modern softwear is used, where the use of multiprogram operational systems and programming systems based on Programming Language 1, FORTRAN, COBOL and others is common for all computer centers.

Works in the field of building automated data banks for the planning organs of the CEMA member nations are directed towards the formation of integrated data bases for complexes of tasks, designed according to unified, methodological principles, which have a common logic structure and which function in the framework of a common system for data bank management.

The proposals under the program for cooperation from 1982 to 1984, developed in the course of discussions and with consideration of the directions in the further works for planning automation in the CEMA country members, include the following basic themes: organizational principles and methodology for the development of automated planning calculation systems; the use of economic-mathematical models to improve planning; problems of information support, the creation of data banks and the development of technical and economic information classification systems and the experience in the practical use of automated planning calculation systems in planning operations.

The conference participants expressed satisfaction in its results, which will facilitate the practical solution of tasks which face socialistic countries in the field of planning modernization based on the use of modern electronic computer technology and economic-mathematical methods.

RAILWAY NETWORK TO BE FURTHER ELECTRIFIED

Bonn INFORMATIONEN in German No 18, Oct 80 pp 14-15

['Background' report by FRG Ministry for Inner-German Relations: "GDR Reichsbahn Network To Be Further Electrified"]

> [Text] According to GDR planning projections for the coming five-year plan (1981-1985) an additional 700 km of GDR Railroad [DR] tracks are to be electrified; so far, only 1,514 km (11 percent) of the total network of 14,199 km have electrified tracks. The GDR hopes that the new measures will result in better energy use of the brown coal which is still available here in abundance and from which approximately 85 percent of GDR electricity is produced, as well as, above all, in reduced imports of expensive fuels needed to operate diesel locomotives, the principal means of transportation.

In a talk to transportation officials in Gotha at the beginning of this year, Minister for Transportation Otto Arndt pointed out that increased conversion of the DR to electrified operation will be the central task for the GDR railway system in the eighties. Arndt said among other things:

"During the coming years, electrification will be the DR's most important rationalization measure to meet growing transportation challenges and, at the same time, to reduce primary energy costs by about 20 percent and labor requirements by about 10 percent by 1985. Because of the high energy effectiveness of electrified railroad transportation and because of the fact that domestic construction capacities and locomotives built in the GDR can be used, the electrification must be considerably accelerated."

With these reequipment measures the DR is trying to take into account the statistically proven facts that--measured in terms of specific energy consumption--the locomotive and transport achievement produced by electric locomotives is superior to all other transportation means.

However, it is only in the last 2 years that the increased electrification of the DR has been intensively promoted. Up to that time--for more than 20 years--preference had been given to the changeover from steam locomotives to diesel locomotives.

This important decision in traffic policy had primarily been based on the fact that compared to electric locomotives the construction of diesel locomotives required considerably less expenditure, and that the use of diesel locomotives was not limited to electrified tracks.

However, the changeover process took a long time because the railroad network had to be expanded first and industry investments were given priority over the modernization of railroad transport. Whereas in 1960 94.4 percent of all locomotives in the GDR were still powered by steam (diesel locomotives: 0.7 percent; electric locomotives: 4.9 percent), the ratio had changed considerably after 10 years: the percentage of steam locomotives had decreased to approximately 42 percent, diesel locomotives had risen to more than 41 percent, and electric locomotives had a share of 16 percent.

The changeover process continued up to this year. According to GDR statistics of 30 April 1980, steam locomotives have decreased to about 9 percent, diesel locomotives have increased to about 72 percent, and electric locomotives to 19 percent.

The preference given during the past years to a changeover to diesel locomotives was the reason that electrification of railroad tracks was only of secondary importance during that time. Since the beginning of the sixties—in 1960 there were 708 km of electrified tracks in the GDR--the speed of electrification of railroad lines has decreased from one five-year plan to the next. Whereas before 1970 650 km of tracks were electrified, the GDR traffic management changed only 97 km of tracks to electricity between 1971 and 1975.

In 1977/78, the absolute low point of electrification efforts was reached. According to official statistics of the CEMA Secretariat in Moscow, a total of only 6 km of electrified tracks was built in the GDR in those 2 years.

According to information provided by the GDR transportation minister, last year the GDR electrified a total of 94 km of tracks through the concentration of investments on main railroad lines that needed improvement, and through several concentrated construction projects.

A comparison between electrified railroad lines in the European CEMA countries shows that the GDR is in last place among them. The percentage ratio of electrified railroad tracks in relation to total track length in the different countries is as follows (as of 1978): Bulgaria 36 percent, USSR 29 percent, Poland 27 percent, CSSR 22 percent, Romania 18 percent, Hungary 17 percent, GDR 11 percent.

The GDR also trails in the speed of railroad track electrification as compared to the construction and modernization efforts by the other CEMA countries. In first place among the CEMA countries in the conversion of railroad tracks to electrified operation are the USSR, Poland and Romania. The difference in the speed of electrification between the GDR and the other CEMA countries during the past 13 years can be seen in the fact that only about one-tenth of the railroad tracks electrified in Poland was electrified in the GDR during the same time.

The respective plans that were now published in the GDR, "to create in the traffic system and other branches of the national economy conditions for a greater speed of

the electrification of the German railroad between 1981 and 1983," do not reveal how these goals are to be reached financially, especially since the railroad tracks to be electrified are first scheduled to be reconstructed into dual tracks.

And even if the GDR should succeed in electrifying an additional 700 km of tracks by 1985, it would still be in last place among CEMA countries in this form of traffic modernization with a ratio of 15 percent of tracks that would then be electrified.

MODERNIZATION OF ENTERPRISES ORGANIZATIONAL SYSTEM DISCUSSED

Budapest PARTELET in Hungarian No 11, Nov 80 pp 12-17

[Article by Istvan Lendvai, deputy chief of department of the Central Committee: "Modernization of the Enterprise Organizational System"]

[Text] The Hungarian economy began to develop rapidly following the liberation. Under the new social conditions, it was a basic goal of industrial policy to develop a large domestic industry which would be competitive even with industrially more developed countries. Following the changes in ownership and the goals of industrial policy, the form and organization of management have also changed greatly. In the course of the last 3 decades, Hungarian heavy industry was developed which is the foundation of our economic development. The establishment of large socialist enterprises made it possible--in spite of all of our difficulties and concerns--to meet the country's rapidly increasing demands, on the one hand, and to make them the bases of the ever more significant international barter and cooperation.

The process of large enterprise development was aided and speeded up from many respects by the centralized organization which took place in the 1960s. The organization of industrial enterprises went through a great change during this time. The extent of centralization is indicated by the fact that the number of enterprises decreased at that time by about 40 percent. As it is well known, the measures were based, among other things, on the fact that organizations which have larger intellectual and material resources can make a better use of both technical and market possibilities.

The facts of the past decades clearly show that the organizations which became larger and more concentrated were better able to meet the demand for growth, especially quantitative growth. This does not mean, however, that the proliferation of large organizations created a favorable situation in every respect. The permanent shortage of certain--mainly consumer--products is also related to the negative economic effects of organizational makeup.

Precisely as a result of the earlier economic development, economic conditions have greatly changed by today. Our special problem today is how to cope with the great changes in the external conditions. Since we cannot change them, we must adapt ourselves--and the various, including organizational, elements and framework--to them.

The new conditions are also reflected by the fact that production became more expensive and the country became more sensitive toward the price changes on the foreign market and toward the market conditions. It is becoming more and more clear that it is increasingly difficult under the new market situation to sell goods made in the earlier production structure with outdated technology and ever increasing costs. It is apparent from this that the country's external and internal economic balance depends on an economy which is updated more rapidly and which is more efficient in production and marketing. To increase the competitiveness of our products and to make the marketing of modern products more efficient, a rapid technological development and a flexible market economy are required.

International competitiveness is, of course, also related to other things beside the problem of modern technology. To find a market or a buyer is not the only objective. We can participate in international barter trade only if our exported products can be sold at good prices or if the cost of domestic goods' production is competitive with prices recognized by the world market at the time of purchase.

One of the basic objectives of the economic management system's present improvement is precisely to increase the proportion of profitable and modern products, and to set the cost of our products to world market prices, i.e., to make the process of production and marketing--from research to marketing of the product--rapid and flexible enough so that it can follow the changing demands of the foreign markets.

Not all production and organizational structures can efficiently serve to improve the economic balance. We want to change this, on the one hand, by eliminating unprofitable activities, by decreasing their central subsidy, and by regrouping them into other, more efficient activities. On the other hand, we want to update the organizational system by making every element of the economy (the enterprises, factories, plants, shops) sensitive to changes in the market, i.e., to economic demands and conditions of the world market which we must face as objective circumstances.

In Line with the Demands of Development

These econo-political goals can be reached through the further development of the entire economic management system. This is what the system's continuous modernization is supposed to aid, and this is the effect of improving the work, and decreasing the staff of central and governmental organs; of changing the organizational structure of industrial management; of the present review of the network of research and organizational institutes and their more direct connection to the production process; and of further improving the enterprises' organizational system to make them more adaptable to the new circumstances.

The modernization of the enterprises' organizational structure has many resources and possibilities for the improvement of economic efficiency. We want to exploit this possibility, on the one hand, by improving and modernizing this structure and, on the other hand, by modernizing the organizational system within the enterprise and the mechanism of internal management.

The enterprise organizational system is too centralized in Hungary today, and large enterprises have the upper hand. At the same time, the well-equipped small and medium-size enterprises are missing. According to international experience, there

is a double tendency in industrial development. On the one side, large enterprises play an increasing role, mainly in areas where they are needed for technological advancement, mass production, and acquisition and maintenance of markets. On the other side, the proportion of small and medium-size factories also increase significantly in the same countries. They play a significant role in domestic supply and, at the same time, serve as a supplementary background industry for the large enterprises. The experience of recent years shows that countries which have a well-distributed organizational structure can adapt themselves better, more easily and efficiently to economic and market conditions.

Notwithstanding, the number of independent economic units in Hungary has shrunk to about half between 1960 and 1980. Most of the small plants and cooperatives run by councils were incorporated by large enterprises as industrial units. This played a role in that the economy's flexibility has not increased adequately, and if we consider that the large enterprises' internal accounting and interest relations hardly improved, i.e., that the large enterprises' factory units are isolated from the effects of the market, then it is clear that this organizational change does not strengthen the economy's adaptability.

But the anachronism of the enterprise organizational structure is manifest in other ways, too. The fact that research and technical development is frequently separated from the enterprise management in a way that alienates the research, developmental and organizational institutions from the production enterprises' system of interest, also has a negative effect on economic efficiency. Their organizational isolation and the lack of mutual financial interest makes the use of research in production processes difficult.

There is a similar concern regarding the relationship of production and marketing as well. The foreign trade enterprises are not only organizationally separated from the production enterprises but their lack of, or weak, organizational relationship is coupled with loose relationships of interest. This weakens the mutual effect of production and foreign trade and decreases the efficiency of marketing.

Evidently, these relations are not so clear and simple in the complex system of economic life. In reality, there are, of course, efficient producing and marketing organizations. There are, at the same time, entirely outmoded and outdated structures as well. In order to be able to assess the goal, essence and meaning of changes that become necessary at various locations, we must look at the problems—and the efforts to change—which characterize the economic processes as a whole.

It also follows from this that we must not change, of course, the entire enterprise organizational system, that we should not consider the operation of large enterprises as inherently faulty, and that we may not hope to solve all of our problems by increasing the number of small and medium-sized enterprises. We are dealing here with a process in which we must find the points where the size and organizational complexity of the enterprise is out of proportion with the demand for market flexibility (resulting from product characteristics), and where the production and marketing process requires another form of organization. At the same time, a network of small and medium-size factories must be created which can, as an integral supplement to the large industry, flexibly follow public demand, the production's cooperational demand, and the possibilities of exporting.

What Changes are Necessary?

Experience shows that we must exercise caution and due discretion in dealing with organizational questions. However, this does not mean that we should overlook the existing and necessary possibilities for change or that we should accept for a long time an enterprise organizational structure which has become obsolete. For this reason, the party and government leadership decided to take more decisive steps toward the improvement of the enterprise organizational system through following the changes in the economy and through keeping pace with the modernization of the economic management system.

An important element of the necessary changes is the examination by government authorities of the enterprises' existing organizational systems. The ministries designated those enterprise organizations where the examination was justified, and they worked out, together with the enterprises, proposals for the necessary changes. Government organs have already discussed and accepted several of these proposals. On the basis of proposals that have already been accepted, several trusts will be closed down. Some units which belong to trusts or large enterprises will become independent enterprises. In some areas, where a close management by a trust is not justified but where some kind of central control and coordination is needed, central offices have been created within the ministries which will coordinate these independent enterprises on the highest level. It is important to emphasize that only those factory units, factories and plants should continue to be independent or be organized into enterprises where the vertical relations between the large enterprise's factory units are loose and deficient, i.e., where the individual factories are, in themselves, closed manufacturing and producing units—or can be made such with little investment.

This process (i.e., the organization of factories and factory units into independent enterprises) cannot be considered either as a general task or as a campaign. The point is much rather that the enterprises' organizational system should change into a flexible and efficient organizational form in a continuous and most suitable way which follows economic changes and is more flexible and adaptable to market demands. Organizational modernization is thus not part of a temporary action, but a constant element of the modernizing economic management, an element which continuously matches the enterprise organizational structure with life's changing requirements—albeit only to the extent that it is necessary and in areas where it is justified.

It is also one of our basic efforts to change the internal economic management system, economic flexibility and interest relation of medium-size and large enterprises so that the factories and factory units, too, can sense the effects of the external market and be able and willing to do management and development work that is compatible with the requirements of real economic conditions. This process cannot be dictated to the enterprises from above. It is the concern and task of every enterprise to establish its own internal mechanism. The government's effort, essentially, is to make the enterprises more willing to introduce changes. This effort must be formulated now not as a wish or a desirable goal but as a definite requirement which at the same time aids the enterprises to develop an internal economic management mechanism that is the most modern and most sensitive under the given economic circumstances.

The development of the internal management system is hindered not only by a lack of knowledge about modern enterprise management, but in many cases also by a fear of sharing authority within the enterprise, and frequently by a lack of confidence in local leaders. To change this, both the social institutions and enterprise managers must adopt a new and modern way of thinking.

The fact that the enterprise's internal management system has hardly improved in Hungary through the years, is mostly connected precisely with problems in attitude and consciousness. Now, when the requirements of both the external economic situation and internal progress mean more stringent tasks for the enterprises, the modernization of the internal mechanism becomes a basic element and essential requisite of staying afloat or moving forward. It must be noted everywhere that human creativity, personal responsibility and action that accepts risks and sacrifice are the things which can lead to a higher level of development.

The reorganization, i.e., the modernization of the internal mechanism of the enterprises is only one aspect of the task. In addition to the large enterprises, there is a need for a significant network of small and medium-size factories. The building of this network is made easier if the independent factories and factory units which secede from the large enterprises are organized into enterprises. But this is not enough. We must find the way to speed up the establishment of small and medium-size enterprises. The expansion of licenses for establishing enterprises is under preparation at present. We want to aid the existing management organizations to create so-called branch enterprises. We also want to aid the cooperative movement to rapidly increase through a simplified process of establishing cooperatives, the number of small units of production and service which are missing from the present enterprise structure. We formulated this unequivocally as a political goal, but the conditions and circumstances of the implementation have only been partly worked out, i.e., will be worked out in the future. However, the process has been started. It may be mentioned as an example that, in connection with the improvement of the industrial services, the Council of Ministers accepted a resolution to develop new and modern forms of service organizations. This way it will become possible to increase the number of industrial cooperatives faster in the future, and to have workers who, in addition to their regular jobs, can work in the services of the so-called specialized groups which function in addition--or belong--to the cooperatives. It will become possible to increase the number of small producers and artisans more rapidly, and to speed up the process of licensing for those industrial workers who want to go into services in addition to their regular jobs.

Strengthening Political Responsibility

It may happen that, because of rigid theorizing, ignoring reality or, in some cases, sheer habits, some people oppose the proliferation of small industry and small plants. It would be a mistake to disregard this. For this reason, the eliminating the onesidedness of the organizational structure and bringing problems out into the open make it mandatory for us to take a clear and definite stand: socialist progress in Hungary is being built at present--and will be built in the future--on industrial mass production. What we are dealing with here is eliminating the onesidedness of organizational structure. We must not forget either that the network of small and middle-size factories, namely, the improvement of industrial and service cooperatives which are filling gaps in public supply and mass industrial production. They are still needed today.

It may also be added that the workers' opportunity for moonlighting and the higher number of artisans entails only insignificant changes in the structure of the national economy as a whole. There is no talk about pushing socialist heavy industry into the background or decreasing the leading role of workers in the heavy industry. On the contrary, the structural modernization of socialist industry as a whole, and the increase of its capacity and efficiency, will in reality strengthen the socialist accomplishments, will boost the efficiency of production, and will improve public supply. This is somewhat similar to the process which took place in the improvement of agricultural household plots and subsidiary enterprises and which--we can already make this statement today--played, no doubt, a large part in the rapid development of Hungarian agriculture, in the strengthening of large agricultural enterprises, and in the outstanding results of the large socialist agricultural enterprises.

Thus the organizational modernization of socialist enterprises is a must for economic progress. For this reason, it is necessary to overcome adherence to the earlier practices, prejudice against change, and fear of problems related to change to remove as many limitations of consciousness and attitude as possible.

Everyone reckons with the fact that such a change entails many human problems, existential concerns, and conflicts arising from the change of habits. But, precisely because the objective economic circumstances necessitate these changes, both the party organizations and social institutions must strive to implement the changes as smoothly as possible, eliciting as few economic difficulties and human conflicts as possible. This is a great task for both the party organizations and the state and economic leadership. It requires a higher [degree of] political responsibility in all areas.

The initial experiences show that the preparations for organizational changes, the understanding of the goals and essence of the changes, and the elimination of unfavorable effects require more care and foresight, and more human concern. It is unacceptable to make preparations for organizational changes without discussing them in time with--and without soliciting the opinions of--the collectives concerned and, especially, the people directly concerned. Even a lack of goodwill originating from clashing interests and temporary opposition may be handled better by openly and clearly stating the necessity and reasons for the change and by involving the people concerned in finding the best solution. It is also unacceptable that in some cases the local party and social organizations are only being informed of finished facts.

Every leader must accept the fact that questions which concern the destiny of people cannot be solved without people. He who acts in such a way, only multiplies his troubles. At the same time, there is another requirement connected with this matter: decisions which are mutually debated, and made after the debate, must be consistently implemented by everyone. A one-sided priority of personal interests and the undermining of the discipline in the implementation cannot be tolerated from anyone. The complex task of the party and social organizations is precisely to help in establishing flexible forms of organization and management that are in the interest of the national economy, to promote social acceptance of correct changes, and to watch for the orderliness and discipline of the decisions' implementation.

SUPPLEMENTARY ACTIVITIES OF LARGE FARMS DEEMED USEFUL

Budapest TARSADALMI SZEMLE in Hungarian No 11 Nov 80 pp 48-53

[Article by Magda Szekelyi, university professor of Engineering and Management Training Institute of Ministry of Agriculture and Food: "On the Supplementary Activities of Large Agricultural Plants"]

[Text] In the period before the socialist reorganization the production of Hungarian agriculture increased annually by 1-1.5 percent. In the last decade the rate of development has doubled this, 3 percent annually, and even exceeded it in the first half of the 1970's. As a result of this our socialist agriculture has given the Hungarian people twice as much basic food stuffs as earlier. At the same time there has been a considerable increase in agricultural and food exports, from which the foreign currency income has increased sixfold since the development of large socialist farms.

A decisive role in these results was played by the fact that the large socialist farms were gradually developed and reinforced, that in addition the forces of production increased to a considerable degree, and that the agricultural production began to be collected by means of basic, modern industrial facilities.

During the last period of this developmental process the importance of the supplementary activity of large farms has increased. The resolution of the 12th MSZMP Congress drew attention to this fact: "From the viewpoint of the national economy it is necessary to support the useful supplementary activities of the agricultural enterprises and cooperatives."*

Hungarian agriculture has rich traditions of supplementary activities. Formerly on large estates and peasant farms alike food preparation, construction material production and construction, timber processing, transportation, marketing, cottage and other small industry activities,

*"A Magyar Szocialista Munkaspart XII. kongresszusanak jegyzokonyve." [The Report of the 12th Congress of the Hungarian Socialist Workers' Party], Kossuth Konyvkiado, 1980, 477 pages.

such as shoeing horses, and repairing machinery and equipment were a considerable part of farm management. For a long time during the period of socialist agricultural transformation the division of labor and specialization had a biased explanation. Partially because of this (and partially as a result of the level of the forces of production at that time) production cooperatives were not allowed to have their own tractors during the 1950's, while by the middle of the 1960's legal measures most decidedly and strictly forbade industrial activity in connection with farming, for example, mixing fodder, repairing machinery and so forth.

Changes were already gradually beginning in all of this during the preparation for the mechanical reforms, while the reforms legalized and opened the road to the development of supplementary activities. By the second half of the 1960's the state farms and the production cooperatives had not only developed agricultural production in the strict sense, but also the industrial service connected with it (for example, mixing fodder), and the processing and the direct sale of food as well. This set the base for the large farms, operating and specializing on a developed technical level, to go into mass production as long as its economic materialization does not at the same time necessitate industrial activities (construction, repair, fodder mixing, other services and so forth) or internal cooperation needed to market finished products, as industrial mass production generally does.

The large-scale production of food and of food stuffs, a signifcant expansion of which followed in this same period, likewise made it necessary for large, modern, farms to provide for the processing of some products and for direct sales to consumers. Without this some of the food produced would spoil, because it would only be possible to use part of the products, very perishable and difficult to transport, which would habitually remain in large amounts on the farms after large-scale marketing to buying agencies and processing enterprises, or because of recurrent difficulties in marketing.

The development of supplementary activities, mainly food industry processing on the spot, has been necessitated on large farms by the fact that significant numbers of village workers have left agriculture and become consumers of agricultural products since the trend towards large farms has become general. Along with the development of the wholesale food industry, the development of the food processing activities of large farms has also become justified because of demands for the elimination of gaps in food supply, for an increase in assortment, and for the production of goods meeting local customs and tastes.

Large farms, primarily production cooperatives, have developed supplementary activities which are not at all connected with the agricultural production. As a result of using our existing capacity (labor force, buildings) to continue these activities (for example, industrial enterprise paid labor), to replace a lack of income or because of the deficient capacity

of small plants, such activities have come into being to satisfy the actual need for products provided in this way. This part of the supplementary activities of large farms serves national economic purposes, and concerns national economic business, while the large farms are based on economic interests.

Under these influences the supplementary activities of large farms developed at a rapid rate at the end of the 1960's and during the 1970's. The increase in enterprise independence with the implementation of the mechanical reform produced significant incentive for this.

From the national economic viewpoint, generally to be considered to be helpful, in individual cases abuses and attempts to profiteer, in connection with outside people, occur along with useful efforts. The party and government resolutions introduced early in the 1970's helped to eliminate these harmful phenomena. Under their influence the supplementary activities developed in a helpful direction, while genuine plant and national economy requirements were satisfied.

The sales income proportion from supplementary activities rose from 37 percent in 1975 to 44 percent in 1979 in the economy of the large farms (state farms and integrated farms, tree farms, agricultural production cooperatives, specialized cooperatives and associations). Almost 80 percent of the supplementary activities of large farms is indirectly connected with agricultural production, and therefore "lengthening it" or serving it yields a more economic organization. These activities include crop shipping and drying, fodder mixing, wood production and processing, viticulture, agricultural machinery repair and agricultural construction, services accompanying the integration of small production and so forth.

The accompanying table (page 4) exemplifies well the total and the proportions of the supplementary activities.

Food industry processing is important in the supplementary activities of the large farms. The farms began to develope this at the end of the 1960's. The state farms have a larger share in food processing, while the agricultural cooperatives have a smaller share. There are also large differences from one megye to another. The production of four megyes (Bacs-Kiskun, Pest, Komarom and Hajdu-Bihar) provide more than half of the income derived from food industry processing. The large farms fulfill a much larger role than the national average in supplying some areas with food, and especially in expanding its variety.

Lumber processing is associated with the forestry of the large farms. At present about 1,000 lumber industry units are busy supplying lumber industry basic materials and semifinished products in the first place, and also packing and other wood products.

Main Indicators of Activities of Large Farms in 1979 (in percentage)

Item	Agricultural Cooperatives	State Farms	Agricultural and Forestry Farms Together
Basic activities	56.5	63.4	57.4
Supplementary activities relating to basic activities	32.2	33.8	33.3
Including:			
- Food industry	4.7	11.6	6.1
- Industry	4.8	5.2	6.3
- Construction industry and transport	3.3	4.1	3.5
- Commercial	19.4	12.9	17.4
Supplementary activities unrelated to basic activities	11.3	2.8	9.3
Including:			
- Light industry	1.2	-	0.9
- Metallurgy and machine industry	4.0	2.1	3.8
- Chemical industry	0.9	-	0.6
- Construction industry and Transport	4.7	-	3.5
- Other	0.5	0.7	0.5
Total of basic and supplementary activities	100.0	100.0	100.0

Source: data from MEM STAGEK

The need for cooperation in construction activities and other industrial service activities keeps increasing with the growth of production and the development of the technical base. The construction industry activities developed rapidly in the 1960's and the first half of the 1970's. In addition practical experience has shown that it is not expedient to squander the construction and other industrial service capacities of the large industries for small-scale village construction and other services, scattered for the most part. It is obvious that the directly concerned large farms themselves organized part of the industrial

services independently, or in the form of joint interenterprise cooperation with economy kept constantly before their eyes.

The large farms unite most of their transport capacity with transport suited for their own, household and auxiliary farms. Transport suited for outside customers constitutes only a few percent of the supplementary activities of the farms, which arouses criticism because a solution to local transport tasks is rather problematic, and at the same time the large farms have considerable free transport capacities available at various times.

In the last few years commercial activity has increased more significantly and its quota proportion in the income from the supplementary activities is greatest. Some 60 percent of the returns in the commercial activities of the production cooperatives come from selling household produce, thus linked to he tasks of integrating and organizing small-scale production. The cooperatives operate approximately 1,400 shops and 1,300 guest units. These units do not have heavy traffic, but their role is important in local supply. In the development of marketing in their own shops the large farms can experience a decline, a block. For example, the number of large farm sites selling vegetables and fruit declined in 1980 from that of the previous year. However, because of the large reduction in the profit margin, a further increase in the share of sales directly through their own shops would be justified.

Some of the large farms, mainly in the megyes of Pest, Komarom and Veszprem, also provided machine, heavy and light industry activities in the 1970's. Most of the state farm production is composed of the manufacture of building elements and agricultural technology equipment, provided by a total of five or six farms. To a greater extent the machine, chemical and light industry activities are also directed towards the supply of tools and equipment necessary in agriculture. They undertake to supply industrial products -- hardware, mass products, clothing, plastics, textiles and garments, lumber and so on -- or to accomplish various operations for which there is a need in the national economy, and accept orders on contract. In many cases they perform work by fitting it in or by paid work.

The authorities compress the supplementary activities unrelated to vertical food production arrangements by putting strict limits on them through legal measures and by the stringent prescription of possibilities, conditions and requirements. The proportion of the supplementary activities not related to basic production, and thus product supply and service outside of food production and paid work suitable for the industrial enterprises and cooperatives, in the entire income is 11.3 percent in production cooperatives, 2.8 percent in state farms and 9.3 percent in all of agriculture.

From what has been said so far, it is quite clear that in recent years in Hungary the production profile of large farms has organically absorbed all of those economic activities which are indispensable for assured performance of large-scale management within the vertical food production arrangements and for lack of worry about expanded reconstruction. Consequently vertically directed cooperation within the large socialist entities is being expanded and diversified. Specialized production organizations developing in raw material production are more and more frequently occupied with processing, packing, stocking and selling directly to consumers. Thus at the same time specialization and vertically directed expansion are characteristic of the change in the production organization of the large farms, giving their management a more specialized, but at the same time more complex, nature.

From the social and enterprise standpoint these changes are mutually beneficial. The vertical development of the farm management, along with the evolution of the specialized production organizations:

-- First of all results in more goods, and contributes to a betterment in the variety of goods supplied, to a supply of better food, sometimes to an expansion of the goods export base, and to reducing import needs;

-- To a significant degree aids in organizing the local industrial, transport, cultural and sanitary services, and helps satisfy needs;

-- By undertaking paid jobs and working them in it usefully complements the production of the extremely concentrated large industrial enterprises, and partially replaces lacking small and medium plant capacities;

-- It facilitates better utilization of the basic working period of workers, and the solution of local labor force economy and employments tasks; and

-- It expands the sources of income, and thus of stockpiling, for the large farms. As a result production increased significantly in many farms and even became more profitable, while at the same time state support associated with harsh judgments decreased or disappeared.

On the large socialist farms specialized large-scale production of goods gradually replaced the traditional, universal type of production characteristic of the peasant branch. In comparison with the universal peasant production, the profile becomes narrower, but at the same time expands in the vertical direction, because the specialized farms strive to develop industrial and service activities which are socially justified and useful from the standpoint of the national economy. Therefore we can justifiably call this process vertical development. As a result the farm economy is not limited to plant culture, animal breeding and gardening in the strict sense. Thus the

demands of consumers can be better adapted to the producers and can be better satisfied.

The supplementary activities of the large farms are developing in a good direction and to a satisfactory extent. These activites of the large farms have also contributed to satisfying national economic needs and to efficiency in management. In recent years the activities mainly related to agricultural production have expanded. Other industrial activities in contract areas have been carried out for the purpose of complementing large-scale production and in the interests of alleviating locally emerging employment difficulties, especially in regions of unfavorable characteristics.

However, during the conduct and organization of the supplementary activities, minor worries have occurred in our times, particularly in service and outside activities organized in Budapest for more distant cooperatives. This occasional case has caused a great deal of harm, particularly in view of the political effect, by circumventing the stipulation of wage regulations and labor force economy. However, there is justification for the supplementary activities carried out away from the site of the large farms (setting up pools, cleaning, service and so forth). It is also true that activities performed outside of the technical site require greater attention on the part of the enterprise leadership, internal enterprise supervision and pertinent authorities.

A great concern of the large farms is that for the most part the supplementary industrial activities are completed in production and service entities mechanized on an outdated low level. A significant part of the machinery and equipment consists of obsolete equipment of zero-value rejected by the industry or of leased equipment. It is characteristic that the productivity of the state food industry providing the majority of the total food industry production, disregarding a few exceptions, is greater than the productivity of the food processing plants of the large farms.

Thus small-scale production is the rule in the majority of the processing plants of the large farms. It is well able to complement the production of the concentrated state processing industry but cannot compete with it. Instead of competition collaboration is desirable and expedient, with its main goal being to meet the everyday needs of the populace, to eliminate gaps, and to usefully complement the activities of the industrial enterprises and cooperatives from the viewpoint of the national economy. A wide area of contact has developed by expanding the supplementary activities between the large farms and the industrial, commercial enterprises and the industrial cooperatives. However, the majority of these contacts are of an incidental and short-term nature. It is expedient to establish long-term cooperation based on joint interests between the large farms and the enterprises (industrial enterprises and industrial cooperatives).

Another important question about the industrial activities of the large farms is improvement in the social circumstances of the workers. At the present time large farms well equipped with social establishments are rare, and in many places the facilities of the industrial production lines are relatively behind the average level. For this reason there is occasional recourse to authoritative penalties. However, the health protection measures aimed at preventing accidents must be maintained everywhere, and a guarantee of these conditions cannot be a subject of deliberation. Improvement in social facilities is an ongoing task.

In recent years the monthly income of those performing industrial work and supplementary activities unrelated to the basic activities on large farms has been an average of 3,118 forints. The composition of the labor force employed in supplementary activities according to specialized training and the production indicators of the work force are less favorable than in industry. Because of seasonable distribution the staff employed in supplementary activities varies from 130,000 to 150,000. In recent years the actual personnel in supplementary activities increased by 9,000-10,000. Of these a total of 3,500 were employed in branches outside agriculture.

The demand and possibilities for further development of supplementary activities deviate widely from branch to branch and from region to region. For example, in the interests of bettering local facilities, there is a great need to expand the food industry processing, the local commercial and guest establishment facilities, and the services for improvement, culture and health. A differentiated approach to construction industry activities is necessary: in some areas it is only necessary to try to make better use of existing capacities, while elsewhere an expansion and development of reconstruction can be justified.

Reexamination and amendment of some stipulations of the economic regulation system are essential for further development of these supplementary activities of large farms. For example, simplification of the regulations referring to price formation and amendment of the production task and the technical development stipulations are justifiable. The licensing process is also very complex and frustrating. There are permits which require almost twenty approvals, and therefore the processing time is 7 or 8 months. It is expedient to do away with such unreasonable brakes as soon as possible.

In accord with the 12th Congress resolution, we have the important tasks of further facilitating better utilization of local possibilities and, from the national economic standpoint, of expediting useful supplementary activities on large farms serving to better satisfy growing and changing demands.

AGRICULTURAL PRODUCTION CAPACITIES TO 1979

Belgrade GLASNIK POLJOPRIVREDNE PROIZVODNJE, PRERADE I PLASMANA in Serbo-Croation No 10, Oct 80 pp 10-16

[Article by Danilo Tomic, M. A.]

[Text] Yugoslavia possesses favorable natural and climatic conditions for the development of agricultural production. Considering the specific natural and climatic conditions, which vary from region to region, in Yugoslavia various types of agricultural production can be organized successfully. Mechanized agriculture has been undertaken successfully in the plains regions of Vojvodina, Slavonia, Macva and Semberija, and in the alluvial plains of the Sava, Morava and Danube.[1] In these regions the most common agriculture is crop production, particularly grain and vegetable crops. The hilly and rolling regions of the country are more suitable for the development of orchards, vineyards and grazing. In addition to very favorable natural and climatic conditions, particularly in land terms, Yugoslav agriculture also has at its disposal other production capacities, whose rational utilization contributes greatly to better and more rapid development of agriculture (including numbers of livestock, equipment for agricultural mechanization, irrigation systems, the rural population involved in agriculture, general and permanent employment, and other factors).

The purpose of the present study is to show the productive capacities of Yugoslav agriculture, with a separate survey of the agricultural status and capacities of Vojvodina, in order to determine a manner for their utilization and trends that have emerged in the postwar development of agriculture. Data have been used from the STATISTICAL YEARBOOK OF YUGOSLAVIA, the STATISTICAL YEARBOOK OF VOJVODINA, and other statistical bulletins, as well as other publications.

Land

Yugoslavia has about 25,580,000 total hectares of land, of which 25,540,000 is dry land. Of this 14,388,000 hectares or 56 percent is used for agriculture, while the remaining 11,152,000 hectares or 34 percent is devoted to other purposes (data from 1975)[2].

The most important factor for the successful development of agricultural production is land, and therefore this factor will be analyzed in detail.

Table 1. Yugoslavia's Agricultural Land by Categories of Use in 1,000 Hectares

Godine 1	2 ukupno	3 Obradive površine					4 Pašnjaci	5 Bara, barice i ribnjaci

Sources: Statistical Yearbooks of Yugoslavia, 1946-1979

Analysis if the data in Table 1 reveals that agricultural lands grew gradually in the period 1946-1960, and declined thereafter.[3]

The increase in agricultural land until 1960 resulted from the expansion of agricultural (largely cultivated) land surface through cultivation of previously non-agricultural lands because of rising demand for agricultural products. After 1960, a decrease in agricultural lands came as a consequence of the more rapid expansion of urban (industrial) settlements, the infrastructure, and other factors.

In the total agricultural land structure, cultivated land is the most prominent category. In 1946, of the total 13.6 million ha of agricultural land, 9.66 million ha, 71 percent, were in the cultivated category, with the remainder of 3.94 million or 29 percent being devoted to other uses. In 1978, of the total 14.436 million ha of agricultural land, 9.939 million were under cultivation, or 65.1 percent, while 4.497 million ha or 34.9 percent were pastures, ponds, marshes and fishponds.

Analysis of the structure of cultivated lands shows that the most important category is plowed crop land and gardens, with much smaller shares devoted to meadows, orchards, and vineyards. In 1946, of the total 9.66 million ha of cultivated land, 7.38 million ha were devoted to crops and gardens, or 76.4 percent. Meadows accounted for 1.73 million ha or 17.9 percent, orchards 298,000 ha or 3.1 percent, and vineyards, 255,000 or 2.6 percent. In 1978, of 9.939 million ha, crop lands and gardens covered 7.204 million ha or (72.5 percent), pastures 2.012 million hectares (or 20.2 percent), orchards 476,000 hectares (or 4.7 percent), and vineyards 247,000 ha or 2.5 percent.

These data show the very slight, insignificant variations in the categories that make up the structure of cultivated lands during the period.

It is also interesting to examine the manner of utilization of crop lands (the planting structure of Yugoslav agriculture); this is shown in table 2.

Table 2: Crop Lands in Yugoslavia According to Use in 1,000 hectares

Godina 1	Oranice i bašte 3	2 Zasejane površine 4 ukupno	5 žita	6 industr. bilje	7 povrtno bilje	8 krmno bilje	9 Rasadnici	10 Ugari i neobr. površine
1947.	7030	6280	5220	331	368	364	2,2	745
1950.	7230	6630	5190	444	465	545	3,2	597

3. crop lands and gardens
4. total
5. grains
6. industrial crops
7. garden crops
8. feed crops
9. nurseries
10. fallow and uncultivated lands

Sources: Statistical Yearbooks of Yugoslavia, 1954-1979

The data in Table 2 show that, of the 7.03 million ha of cultivated land, 6.28 million ha or 89.3 percent were planted, while 747,200 ha (or 10.7 percent) were nurseries or fallow land or were not utilized (data for 1947). In the same year, of 6.28 million ha of planted land, 5.22 million ha or 83.2 percent were sown with grains, 331,000 ha or 5.2 percent with industrial crops, 368,000 ha or 5.8 percent with garden crops, and 364,000 ha or 5.7 percent with feed crops. In 1978, of the total 7.204 million ha cultivated, 6.524 million ha or 90.5 percent were planted and 670,000 ha or 9.5 percent were uncultivated, fallow, or nurseries. Of the 6.524 million ha planted in 1978, 4.429 million ha or 67.8 percent were sown with grain, 540,000 ha or 8.3 percent with industrial crops, 651,000 or 9.9 percent with vegetables, and 904,000 ha or 12.5 percent were sown with feed crops.

The great preponderance of grain crops, on the one hand, and the minimal plantings of industrial crops, vegetables and feed crops on the other, can be discerned in the planting structure of Yugoslav agriculture. In other terms, the relatively extensive development of agricultural production in the post war years can be seen. In the last several years, however, and particularly since 1973, the opposite trend can be noticed. Changes are occurring in the planting structure, with the surface planted to grains declining (by about 1.2 million ha in 1978 compared to 1960), while the land planted with industrial crops, vegetables and feed crops is constantly on the rise. This results from the accelerated agricultural and economic development of the country as a whole. Needs for various high quality processed

agricultural products are growing, and changes in the planting structure to meet these needs are becoming increasingly a necessity. Besides this factor, yields from hybrid plants, particularly grains, have been increased significantly per unit of land, thus assuring adequate quantities of these products even from reduced amounts of land.

Since Vojvodina has significant production capacities in this area, we will present its agricultural and cultivated land data and examine the differences in the manner of use of these hectares in Vojvodina as compared to Yugoslavia as a whole (Table 3).[4]

Table 3. Agricultural Land in Vojvodina by Category of Use in 1,000 ha

6. orchards
7. vineyards
8. meadows
9. grazing lands
10. ponds
11. fish ponds

Sources: Statistical Yearbooks of Vojvodina, 1964-1979

In 1964, of the total of 1.829 million ha devoted to agriculture, 1.653 million ha or 90.3 percent were cultivated, while the remaining 176,000 or 9.7 percent consisted of grazing lands, ponds, and fishponds. In 1978, of a total of 1.798 million ha of agricultural land, 1.628 million ha or 90.5 percent was cultivated, while the remaining 170,000 ha or 9.5 percent were pastures, ponds and fishponds.

The data in Table 3 show that in 1964, of the total 1.653 million ha under cultivation, crop lands and gardens accounted for 1.578 million ha or 95.4 percent, orchards for 10,000 ha or 0.6 percent, vineyards for 25,000 ha [illegible].5 percent, and meadows for 40,000 ha or 2.5 percent. The situation had no[illegible]nged markedly by 1978: of the total of 1.628 million ha under cultivation, crop [illegible]nds and gardens accounted for 1.564 million ha or 96.0 percent, orchards for 12,000 ha or 0.7 percent, vineyards for 19,000 ha or 1.2 percent, and meadows for 33,000 ha or 2.0 percent.

If we compare the data of Table 3 with those of Table 1, we note that crop lands and gardens are much more predominant in Vojvodina (about 95 percent of all land)

as the method of use of cultivated lands than is the case for Yugoslavia as a whole (where about 70 percent of the arable land is in crops and garden produce). On the other hand, orchards, vineyards and meadows are much rarer in Vojvodina than in Yugoslavia as a whole (when Tables 1 and 3 are compared).

The manner in which cultivated lands are used in Vojvodina is shown in Table 4.

Table 4. Cultivated Lands According to Use in Vojvodina, in 1,000 hectares

Sources: Statistical Yearbooks of Vojvodina, 1964-1979

In 1964, of the total 1.58 million ha of cultivated land, 1.571 million ha or 99.4 percent were planted, while 9,000 ha or 0.6 percent were fallow or unused. Of the 1.571 million ha planted that year, 1.17 million or 74.5 percent were sown with grains, 174,000 ha or 11.1 percent with industrial crops, 66,000 ha or 4.2 percent with vegetables, and 161,000 ha or 10.2 percent with feed crops. In 1978 the situation was changed somewhat. Of the total 1.522 million ha cultivated, 1.042 million ha or 68.5 percent were sown with grains, 314,000 or 20.6 percent with industrial crops, 82,000 ha or 5.4 percent with vegetables, and 86,000 ha or 5.6 percent with freed crops.

These data show a slight decline in the amount of land planted with grains in Vojvodina, while the land planted with industrial crops has been growing significantly. That can be explained by the more rapid development of the food processing industry, chiefly through the construction of new sugar refineries and oil producing plants and the reconstruction of existing facilities. Lands planted with vegetables have shown a moderate growth, while the land sown with feed crops has declined constantly as a result of the diversification and decline in the number of livestock in Vojvodina.

Since agricultural production in Yugoslavia is organized into both social and private holdings, Table 5 shows the relationship between these categories of cultivated land in Yugoslavia.

Sources: Statistical Yearbooks of Yugoslavia, 1954-1979

In 1954, of the total of 9.98 million ha of cultivated land, 921,000 ha or 9.2 percent was in social ownership, while 9.06 million ha or 91.8 percent was in private hands in Yugoslavia. In 1978, of the total of 9.936 million ha of cultivated land, 1.58 million ha or 15.9 percent was socially owned, and 8.356 million ha or 84.1 percent was owned by private individuals. That means that lands in social ownership were constantly increasing in the period 1954-1979, while lands in private hands were decreasing. These two opposite manifestations were the consequence of the development of social agriculture and the gradual socialization of individually owned agriculture. These factors are mutually related and interdependent. The development of one manifestation in the future can take place chiefly at the expense of the course of the other. Due to the slowness with which socially owned lands have increased (primarily by purchases of land from individual households, abandonment, noncultivation and irrational utilization of significant amounts of individually owned households have occurred (particularly where such households belonged to aged owners, as well as lands in hilly and rolling regions are concerned).

In that connection, Professor P. Milenkovic writes:

"Socially owned lands do not have much interest at the moment in purchasing land in general, since through the production of their usual crops they achieve relative high earnings per employee, and are not obliged to seek to expand their land holdings. Besides that, the purchase of new lands would require new finances, and these cannot be obtained on favorable terms. Therefore, many social cooperatives make it almost a condition for acceptance of new land that the agricultural worker assure cheap bank financing, with low interest and long terms of repayment (such as 20 years at 3 percent interest). The society must be aware of this situation, for if not the entire opportunity can be missed. Such social situations will probably have their weight as well, but in the last analysis, no one has the right to expect that a particular economic organization will resolve a social problem in its area of involvement in the name of the entire society without broader social solidarity, or without acting in its own economic self-interest."[5]

Therefore, in the future organized expansion of cultivated land in social ownership, primarily by the purchase of land from elderly owners and by the introduction of cultivation to new areas, must be the constant concern and the obligation of socially owned land holdings and of the broader social community.

Table 6 presents methods employed for expanding the cultivated lands of socially owned holdings.

The data in table 6 permit the observation that leasing and purchasing land and introducing new lands into cultivation have been the most frequent ways for expanding the total cultivated land in socially owned holdings.

The Number of Livestock

Animal grazing is a very important branch of agricultural production where noticeable results have been achieved. Due to the lack of long-term systemic measures and the slowness in adopting such measures, livestock production has constantly fluctuated and lags behind crop production.

The data of tables 7 and 8 lead to several conclusions:

1. The number of livestock in Yugoslavia has varied considerably in regard to types of livestock and of land holdings.

2. The number of cattle in the period examined has ranged from 488 to 580 head per 1,000 hectares of arable land.

3. The number of cattle on privately owned holdings also varies, but it is relatively higher and fluctuates between 513 and 644 head per 1,000 hectares of cultivated land.

4. The number of livestock on socially owned holdings varies a great deal fluctuating between 156 head per 1,000 ha of cultivated land in 1955, to 490 head in 1960, with the number per 1,000 hectares being 221 in 1975. A similar situation is found for other types of livestock. The variations are particularly great for swine, and also on socially owned land. The number of horses and sheep has been steadily declining on both socially and privately owned land, while the total number of poultry has increased on both types of holdings. The causes for these fluctuations in livestock production should be sought in the destimulative measures of economic policy, in unprofitable production, insufficient organization of markets, and insufficient bonds between producers of livestock and animal products on the one hand, and processors and consumers of animal products on the other. Particular difficulties are to be found in the unfavorable relationship between the prices for fodder and for animal products.

The situation concerning livestock in Vojvodina coincides with that in Yugoslavia as a whole (see tables 7, 8, and 9).

It is interesting to note the greater capacity for adjusting to livestock market changes by privately owned holdings both in Yugoslavia and in Vojvodina.

The Mechanization of Agriculture in Yugoslavia

In terms of the number of tractors, combines and trucks, the mechanization of Yugoslav agriculture has been increasing constantly.

Table 10. The Mechanization of Yugoslav Agriculture in Major Categories

Sources: Statistical Yearbooks of Yugoslavia, 1964-1978, for columns 1, 2, and 3; the data in columns 4, 5, and 6 were prepared by the author.

Analysis of the data in Table 10 shows the rapid growth in the number of tractors from 20,500 in 1958 to 296,825 in 1978. This growth in the number of tractors (which increased 13 times) resulted from the rapid process of so-called "tractorization" of privately owned land. The number of tractors on socially owned lands grew until 1966, but since then it has shown a tendency to decrease, although the number of horsepower per hectare of cultivated land has grown. If the ratio of cultivated hectares per tractor is considered, it is seen that in 1964 there were approximately 273 hectares per tractor in Yugoslavia, with 35.25 ha per tractor on socially owned lands and 1,755 ha per tractor on privately owned lands. By 1978 this situation had changed markedly, so that throughout Yugoslavia there was one tractor for every 35 hectares of arable land (about 60 hectares in the socialized sector and about 34 hectares in the private sector).

The number of combines tended to grow in the period from 1958 to 1968, and thereafter, to decline slightly.

The number of trucks, which have the important role of shipping agricultural products, increased until 1974, and then stabilized. The status of mechanization of agriculture in Vojvodina is shown in Table 11.

Table 11 shows that there was a more or less constant number of tractors and combines on socially owned land holdings. On privately owned lands, the number of tractors increased 4.2 times and the number of combines 6.3 times in the period from 1972 to 1978. In 1972, in Vojvodina there were 72.5 hectares of cultivated land per tractor, with 55 hectares per tractor on socially owned lands and 88 ha per tractor on private lands. In 1978, there were about 27 hectares per tractor, with about 57 ha per tractor on socially owned lands and about 20 ha per tractor on private lands.

Irrigation and Land Drainage in Agriculture

There are favorable circumstances for irrigation of cultivated lands in Yugoslavia. Thanks to the construction of the Danube-Tisza-Danube canal and the rivers Sava, Tisza, Morava and others, it would be possible to irrigate much more land than is presently under irrigation. That development would certainly have a positive effect on the development of agricultural production table 12).

8. crop lands and gardens
9. orchards
10. vineyards
11. meadows and pastures
12. preliminary data

Sources: Statistical Yearbooks of Yugoslavia, 1956-1979

The total irrigated surface is on the increase. In 1955 only 97,385 hectares were irrigated, and of those 95,878 ha (98.5 percent) were done by surface irrigation and only 1,507 ha (1.5 percent) by sprinkler systems. In 1978, the total irrigated hectares reached 144,502, of which 99,774 ha or 69 percent were surface irrigated and 44,728 ha or 31 percent were under sprinkler systems. In 1955, the total 97,385 irrigated hectares included 78,437 ha or 80.5 percent crop lands and gardens, 2,896 ha or about 3 percent orchards, 157 or 0.2 percent vineyards, and 15,895 ha or 16.3 percent meadows and pastures.

In 1978, of the total 144,502 irrigated hectares, 106,572 ha or 73.7 percent were crop lands and gardens, 12,133 ha or 8.4 percent orchards, 16,707 ha or 11.5 percent vineyards, and 9,090 ha or 6.3 percent were meadows. Comparison of the data shows that the share of crop land, gardens, orchards and vineyards increased in the irrigation system, while the share of meadows and pastures in the total declined. Expressed in percentages, in relationship to the total irrigated lands, those consisting of crop lands, gardens, and meadows are less than previously, while irrigated vineyards and orchards are much better represented in 1978 than in 1955. It can be concluded that in Yugoslavia as a whole and in Vojvodina, the irrigation of crops is given little attention, with only 1-1.5 percent of cropland being irrigated (compared to 15 percent in Italy, 20 percent in Greece, and 30 percent in Bulgaria). Despite significant capacities, the irrigation system and the drainage system (see Tables 13 and 14) in Yugoslavia are insufficiently utilized, and use of the drainage system is not used effectively enough.

** Data until 1963 include only water management organizations, while those for 1964 and thereafter also include socially owned agricultural organizations.

For these reasons, every year there are floods and resultant erosion in river valleys and particularly in hilly regions, where erosion brings severe damage to Yugoslav agriculture.[6]

Keeping in mind the available irrigation and drainage capacities and the great losses that result from their ineffective and untimely use, it is clear that much more attention must be devoted to the utilization of the irrigation and drainage systems. In the future, the irrigation system must be used more to cultivate industrial crops, vegetables and feed crops.

The Agricultural Population; Total Employed and Permanently Employed Workers

In the postwar period there has been both an absolute and a relative decline in the rural population of Yugoslavia (from 75 percent in 1946 to 35 percent in 1975). This has resulted from the rapid industrialization process and accompanying reduction in the agrarian populace of the country. The possibility that a steadily declining agricultural population will produce increasing amounts of agricultural products and satisfy the needs of a constantly growing population underlines the growth of productivity in Yugoslavia agriculture.

Comparison of total employed and permanently employed on socially owned lands in Yugoslavia reveals that the number employed grew until 1965, and thereafter declined. Regarded from the viewpoint of socially owned lands, this phenomenon is justified, but from a broader social viewpoint it is not. It is true that the development of industry and other economic activities requires that the surplus rural population be absorbed in these functions, but until these activities train the unemployed to fulfill these tasks, places should be found for the rural unemployed in agriculture through the intensification of production.[7]

It is unacceptable that in Yugoslavia, according to statistical data, some 670,000 hectares of arable land remain unworked. (and empirical data indicate an even higher total), there are some 740,000 unemployed, of whom about 430,000 are workers in the semi-skilled and unskilled categories. The introduction of cultivation on these uncultivated lands could contribute to the employment of a definite number of the presently unemployed.

The presence of a hereditary values system in Yugoslavia degrades physical work in general and agricultural labor in particular. For that reason the affirmation of labor (particularly physical and agricultural work) must be assured a respected place on the socioeconomic system, so that it, as a source of income, would eliminate all other possibilities from competition and become the main factor in social prestige.[8]

The number of agricultural specialists, veterinarians and economists employed in socially owned land holdings has been growing steadily, both in total numbers and per 1,000 hectares of cultivated land (see Tables 15 and 16).

FOOTNOTES

1. Since Vojvodina has especially great production potential, a special survey of its agricultural capacities will be given.

2. Total land is taken to mean land surface including land under domestic bodies of water.

3. Agricultural areas shown in Table 1 include farms as well as opstina grazing and meadow lands and other land under socialized ownership.

4. Agricultural lands in Table 3 include lands in agricultural households and lands in nonagricultural households.

5. For more details see Professor Milenkovic's study: "Problems of Social Insurance for Farm Workers," which is a part of the collective work Basic Directions of Development of the Agroindustrial Complex in Vojvodina, Novi Sad, 1978, p 312.

EXPORT OF FOOD--PROBLEMS, POSSIBILITIES

Belgrade GLASNIK POLJOPRIVREDNE PROIZVODNJE, PRERADE I PLASMANA in Serbo-Croatian No 10, Oct 80 pp 34-37

[Article by Milenko Nikitovic]

[Text] Not long ago (and perhaps at an untimely moment) Yugoslavs began to state and proclaim that "food is our oil," and to determine to export food, so that in exporting they might reach a total income of one or 2 billion dollars.

However, in order to export, it is necessary to have, and in order to have, it is necessary to produce. Considering the present situation, Yugoslavia is not producing enough of certain most important products even for internal needs; rather, these products are being imported. That is incontestable. It is logical that export plans, whether they include a half, 1 or 2 billion dollars in value, should be based on the needs of the country and on its production plans.

Unfortunately, despite all the proclamations on food exports, the official projection for the Yugoslav five-year plan on the development of the agro-industrial complex from 1981 to 1985 does not foresee any significant food exports. On the contrary, the "Basic Directions of Development of the Yugoslav Agro-Industrial Complex for the period 1981-1985," presented at the Yugoslav conference on food in Belgrade in March, expressed more doubt about the possibilities of expanding Yugoslav agricultural exports, with the statement "that we should not nurture any unusual expectations recording our exports of agricultural and processed food products."

Among other things, the projection plans for annual exports in the coming period totalling:
60,000-70,000 tons of meat;
0.5 million tons of corn; and
20,000-25,000 tons of tobacco.

For the satisfaction of domestic demand, it is estimated that in the coming period the following quantities will be needed:
6 million tons of wheat;
11 million tons of corn;
about 1.5 million tons of meat;
900,000 tons of sugar;
500,000 tons of fat, etc.

As an argument for the impossibility of increasing Yugoslavia's agricultural exports, the example is cited of the decline in the volume of exports of the 7 most important products during the period 1968-1977.

It is understandable that such an evaluation of the possibility of Yugoslav agricultural exports is not only contrary to the urgent needs of the economy, as well as the status of the Yugoslav foreign trade balance and balance of payments, but also that it does not correspond to the situation on world food markets. To be specific, today Yugoslavia could [theoretically] sell in foreign markets more than 100,000 tons of meat, several hundred thousand tons of sugar, grain, and other commodities.

Why did Yugoslavia export less in the period 1968-1977? With the exception of the crisis from July 1974 until the end of 1975, provoked by the decision in Brussels to embargo exports of baby beef from countries that were not members of the EEC, for all the years prior to 1974 and after 1975 Yugoslavia exported as much baby beef, pork and poultry as it had available for export. There was no grain for export until 1977, when 200,000-300,000 tons were exported, only to have to import corn 6 months later. Throughout the period there was simply no sugar, oil, lard or poultry and very little pork, available for export. Yugoslavia exported its first tons of sugar in July 1979. On the contrary, imports of these commodities (some constantly and others frequently) were regularly necessary.

The exports of pork are a typical example; they have followed the pattern below in the last 7 year (in 1,000 tons):

1973	1974	1975	1976	1977	1978	1979
--	2	18	5	--	10	--

It should be stated that pork was actually imported in 1977 and 1979. It is, however, certain that Yugoslavia could market 30,000 to 50,000 tons of pork in foreign markets annually.

It should be pointed out that in 1965 Yugoslavia exported a total of 120,000 tons of all types of meat, which at today's prices would be worth 220 million dollars, or 60 percent of the total exports of animal products in 1979.

In 1979 Yugoslavia exported:

45,328 tons of yearling beef;
3,052 tons of lamb;
203 tons of poultry; and
24 tons of pork; totalling 48,507 tons

That same year imports were:

47,772 tons of beef;
3,718 tons of pork; and
82 tons of poultry; totalling 51,522 tons

Thus regarding meat, where Yugoslav exports have always been the greatest, the balance in terms of volume varies, or is even a negative one, where for the first time since World War II imports of meat surpass exports.

The record years for exports of animal products should be recalled, since they represent the limits that can be achieved and can be compared with the exports of Europe's largest meat exporters. According to years and types of stock and meat, these records are as follows:

live cattle	1972	171,000 head
baby beef meat	1978	82,000 tons
pork	1965	56,000 tons
canned meats	1965	38,000 tons
live sheep and lambs	1971	206,000 head
lamb and mutton	1966	5,000 tons
horses	1978	43,400 head

If the above quantities are calculated at today's prices and other articles are added to them, the total livestock products exported would be valued at 700 million dollars, or twice the 1979 total. If other agricultural exports were added, a total of 1 billion dollars in exports would be very nearly acheived. It cannot be explained, however, why less exports of meats are included in the plan for 1985 than were attained in the past decade.

It is significant to point out that the projected exports of animal products for 1981-1985 of the Foundation for the Advancement of the Production and Marketing of Livestock and Animal Products plan exports worth 750 million dollars in 1985. This figure includes the quantities of 86,000 tons of yearling beef, 20,000 tons of pork, 10,000 tons of poultry, etc., for a total of 127,000 tons of meat, along with increased exports of live animals, canned meat and other products.

In order to complete the data necessary to perceive the actual situation in the Yugoslavia balance of imports and exports of food, the following figures are presented to show food imports in 1979, in millions of dollars:

Grains and processed grains	270
meat and processed meat products	63
live animals	9
milk products	8
sugar and processed sugar products	9
fish and processed fish products	22
animal feeds	87
fruits and vegetables (largely tropical fruits)	155
coffee, cocoa and spices	280
other products	47
Total	950 million dollars

A summary of exports and imports of food is shown in table 1, in million dollars:

Table I

Exports		Imports		Balance	
1978	1979	1978	1979	1978	1979
686	676	604	950	+82	-274

In contemplating exports and imports of food, the unavoidable conclusion is that Yugoslav agricultural exports have been declining in the past decade. The reason is that production is insufficient even to satisfy domestic demand, so that Yugoslavia has been forced to import many goods that could be produced there. In today's world there are purchasers of meat, sugar, oil and grains, but Yugoslavia has thus far had rather limited quantities for export, so that without higher production, even in the future it will be impossible to count on increased agricultural exports.

Another question is why the programs and objectives established in the Agreement on the Bases of the Yugoslav Social Plan for the Development of the Agroindustrial Complex for 1976-1980 have not been accomplished. Those programs and objectives were both carefully wrought and grandiose, so that, in a word, their realization would have solved many problems and dilemmas related to the agrocomplex.

According to the Agreement, the development of agricultural and food production would have been directed to satisfy the growing domestic needs of Yugoslavia, gradually reduce and eliminate imports of agricultural products that can be produced domestically in sufficient quantities, and facilitate economically effective and socially justified exports at an average annual rate of 10 percent.

Without presenting quantities for each product, it can be said that among other things, planned corn exports would amount to 1.5 million tons and wheat export to 0.5 million tons. These goals and objectives were completely realistic and correctly reflected the country's needs. They were, however, achieved only in part, for growing demand was satisfied by imports and imports were not decreased nor eliminated, but rather increased, while exports did not increase but rather, they became smaller from year to year.

Certainly two poor harvests are not the only cause of this situation; rather, a number of factors are involved, beginning with increasing uncultivated land or from the opposite viewpoint, decreasing amounts of land in cultivation, and including the slowness of adding land to the social sector, credit policy, low yields from the lands of private producers, and other factors.

For a more objective evaluation of Yugoslav plans and programs, always keeping in mind the country's needs and the needs for exports, it is useful to compare the planned quantities of agricultural products in the Agreement for 1976-1980, anticipated results for 1980, and the plan projections for 1981-1985, presented in Table 2.

The Projected Agreement for 1981-1985 in comparison to the Agreement for 1976-1980 reveals several factors, primarily in relation to the needs of the country and to export.

It must immediately be stated that the planned amounts of grains and meats absolutely preclude the possibility of any significant increases in agricultural exports; indeed the physical quantities of exports will continue to decline. Therefore, the conclusion must be that the production of meat and grain must be increased so that growing domestic demand can be satisfied and significant quantities accumulated for export, and so that agricultural exports can rapidly reach and surpass the constantly mentioned level of 1 billion dollars.

The commodities and quantities that should be produced are chiefly the following:

13 million tons of corn, of which 10-10.5 million would be for domestic needs, and 2.5-3 million tons for export;

approximately 7 million tons of wheat, of which 6 million would be for domestic needs and 1 million tons for export;

about 1,550,000 tons of meat, of which about 1.4 million tons would be for domestic needs, and 155,000 tons for export; and

about 300,000 tons of sugar for export.

The manner in which these record levels of production of particular commodities can be achieved is a topic about which many doctoral dissertations and masters' theses have been defended, yet the production of wheat has never surpassed 6 million tons and corn production has never approached 11 million tons.

To answer the question as to whether the indicated production quantities are realistic and attainable, is necessary not only because of the pressing needs to export but also because Yugoslavia is obliged to reach higher production and productivity by the 9 million hectares of cultivated land, and the total of 14 million hectares of agricultural land (including cultivated land and pastures), by the number of persons employed in agriculture, and by the results achieved so far in crop and livestock production.

These goals and objectives must, however, be accepted by everyone, and that suggests the mobilization of all forces in all sectors and positions, from production and science to specialists in economic associations, republic and federal secretariats, to the banks and all those who in any way are involved in or related to agricultural production. In other words, crop and livestock production must reach hitherto unattained levels of production, but levels that are not unrealistic or unattainable.

Without grain exports and increased meat and live animal exports, it is impossible to achieve the fervently awaited billion dollar goal. Agricultural exports account for only 10 percent of total Yugoslav exports, eg., in 1979 they amounted to $650 million of the total $6.5 billion exports. But agricultural exports from Hungary have exceeded $1.5 billion for a long time. Romania and Poland export $1 billion each, not to mention the Federal Republic of Germany, which realizes $4.5 billion from agricultural exports, or France with $8 billion, or the United States with $38 billion in agricultural exports.

It was stated previously that there are enough buyers in today's world for grains, meat, sugar and oils; that means that sufficient quantities of foods should be produced for domestic needs and for export. The quantities produced for export should be:

2.5 to 3 million tons of corn;

about 1 million tons of wheat;

155,000 tons of meat; and

about 300,000 tons of sugar.

It is, of course, easier to come to these conclusions on paper than to produce the goods. Certain preconditions must exist in order to produce the indicated quantities in actuality; the domestic resources of Yugoslav agriculture must be found and the hindrances overcome that have prevented our surpassing the 6 million ton wheat barrier and the 10 million ton barrier for corn.

Further Socialization of the Land

The structure of land ownership and the 82 percent share of the private sector in cultivated land has a decisive role in the volume of agricultural production. It is certain that every percentage point of increased land in social ownership brings greater yields and thereby, greater surpluses for the market.

Of the total 7.1 million hectares of cultivated crop land, the private sector holds 5.78 million hectares, or 81.5 percent, while the social sector has 1.32 million, or 18.5 percent. It is believed that if the social sector had about 700,000 additional hectares, it would be able to solve the problems related to supplying the domestic market and food imports.

Expansion of land in the social sector averaged about 45,000 hectares annually until 1970. After that there was little change, so that currently the expansion does not amount to even 10,000 hectares per year. The reason for this is found in the more stringent conditions for financing purchases of private land, while economic organizations do not have their own capital available for this purpose.

There are other problems as well. One prominent economist in eastern Serbia explained the types of difficulties encountered by his work organization in purchasing land. The organization purchased 1,000 hectares of private land, and then had to plow, seed and cultivate it. They went to a tractor factory seeking to buy tractors on credit. There they were asked to put up 30 million dinars if they hoped to obtain tractors. Then they went to a chemical fertilizer plant, where they were expected to put up 10 million dinars. They received similar requests from the sheet metal factory and other suppliers. The economist concluded by saying that their bank could not keep up with these investments, because it did not have the resources.

The plan projection for 1981-1985 anticipates that by 1985, some 150,000 more hectares will be socially owned. This increase does not even approximate the country's needs, for it is the social sector that provides market surpluses and that should eliminate imports of food and increase exports.

It is obvious that the instruments of current policy do not favor land purchases, despite the fact that further socialization of the land has a pivotal role in Yugoslavia's future volume of agricultural production and food balance. Increasing the maximum limit for land holdings in individual regions of the country can provide certain results, but the social sector has the role of revolutionizing agriculture, not only by involvement of science and the application of modern agrotechnology, but also by producing the quantities of foodstuffs that are lacking in Yugoslav food balances, both for domestic needs and for export. For these reasons, further socialization of the land should be promoted at the most rapid possible tempo, and all current regulations must support that process.

The Reduction of Agricultural Land

This question is also of exceptional significance for the continuing development of agricultural production. Specifically, the reduction of agricultural land has been under way, and from 1961 to 1977 it has averaged approximately 40,000 hectares per year. This trend will continue in the coming period largely in favor

of the construction of the infrastructure, of industrial installations, the growth of urban settlements, and the like.

This fact must be kept in mind, for crop lands, for example, have decreased by nearly 600,000 hectares in the last 20 years.

Uncultivated Lands

According to official data, more than 600,000 hectares of crop lands are not being cultivated, and about 2 million hectares of pasture that are socially owned are not included in organized production. This fact is certainly the most unfavorable and most drastic one regarding the agricultural problems mentioned above. It is striking that Yugoslavia imports grain, meat, butter and other commodities while it has 600,000 hectares of uncultivated land. That is uneconomic land management that requires, not as often is said "suitable solutions," but simply that that land be put into service as urgently as possible. In this area the social sector is most called to execute its social role, regardless of whether the land is in the private or the social sector.

Analysis of the data presented force the conclusion that in the past period not everything that could have been done was done, particularly regarding the purchase of private land and the cultivation of unused lands. Much depends on these factors for supplying domestic markets, eliminating food imports and increasing agricultural exports. It cannot be disputed that these are questions that require determination of policy by the highest agencies of the Yugoslav social community, and the passing of suitable measures for the entire territory of the country. Associated labor will then be obliged to bring such policies to life diligently and comprehensively.

Increasing the Number of Livestock

When the objective of increasing meat production to 1,550,000 tons in 1985 is proposed, of which 155,000 tons is to be exported, the first requirement is that the number of livestock, and particularly of cattle, be increased.

The question of increasing meat production is specifically related to livestock production. Analysts would immediately point out that only 55 percent of the total cattle become full-grown, and the slaughter of calves weighing less than 100 kg accounts for 44 percent of the total cattle slaughter; this is unique in Europe. Because of the slaughter of large numbers of calves, the average weight of butchered cattle in Yugoslavia does not exceed 140 kg, while the average for other European countries ranges from 200 to 240 kg.

There is a similar situation regarding pork production. In 1978, 14.4 million hogs were slaughtered, of which 36 percent were young pigs; this does not occur in any other country. As a result, the average weight of all slaughtered hogs is only 34 kg, while those slaughtered at slaughterhouses average 77 kg. Therefore, along with other measures, much more rational slaughter plans are necessary that would greatly reduce the number of calves and young pigs slaughtered.

Similar problems exist with sheep raising, alongside other problems. Primarily, the number of sheep is rapidly declining, for from 11 million in 1969 the total number of sheep in Yugoslavia is 7.5 million today, despite the fact that throughout the rest of the world, including Australia, Great Britain, the FRG and the USSR, the number of sheep is on the rise.

The Private Sector

The question is how can the private sector be activated and urged to greater production? The problem includes matters of volume, time period and tempo by which the private sector can contribute to a significant increase in food production.

With a potential of 9.7 million hectares of land, of which 5.8 million are crop lands (accounting for 81.5 percent of all crop lands in the country), the private sector can make a significant contribution to agricultural production without a doubt. That means that it is necessary to perfect measures and regulations relating to this sector with the goal of stimulating individual producers to achieve greater production of those commodities that are in short supply and that are foreseen in the social plans.

Yet planned objectives and proportions in social plans are not transformed into plan obligations for those responsible for the planning in either the social or the private sector. Every plan is good if it is fulfilled, attained and if it contributes to the increased material welfare of the society.

The Agreement on the Bases of the Social Plan for the Development of the Agroindustrial Complex for 1976-1980 also had very well stated and formulated objectives, the plan was ambitious and promised much. The Agreement, however, was only partly achieved. For example, it happened that one socially owned holding with 30,000 hectares of public land liquidated its livestock as an unprofitable activity, because crop cultivation assured definite accumulation of capital and income, while livestock raising could even result in losses.

The social sector, however, cannot ignore the needs of the society, and it is obliged to produce the quantities and assortment anticipated by the social plans, always for society's needs. Naturally, it is obvious that the society must provide all the conditions for the set production levels. In the opposite case, free and elemental laws will rule the market, and some commodities will be in short supply while there are surpluses of others. That means that not only the profitable goods must be produced, but all the goods the society needs for its nourishment and for export.

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Indexes to this report (by keyword, author, personal names, title and series) are available from Bell & Howell, Old Mansfield Road, Wooster, Ohio 44691.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

BRIEFS

NEW PRAGUE PORT--The fluvial port in Prague-Holesovice can no longer serve the volume of the current shipping, and construction of a new port in Radotin, south of Prague, will begin in 1982. The new 21-berth facility will be one of the most modern ports in Central Europe, capable of handling 3 million tons of goods yearly. The port should become operational after 1990. [Bratislava PRACA in Slovak 10 Dec 80 p 2]

CAR SALES DROP--The price increase of gasoline in the CSSR has not only resulted in lower gasoline sales, but also lower sales of cars. Consequently a 9.2 percent drop in car sales has been registered in 10 months of 1980, the figures being about the same for both new and used cars. Car repair facilities have less customers and the Motokov enterprise has on hand thousands of unsold cars. [Prague MLADA FRONTA in Czech 9 Dec 80 p 2]

GERMAN DEMOCRATIC REPUBLIC

IPW DIRECTOR DISCUSSES PROBLEMS OF STRATEGIC BALANCE

'Insane Strategy,' Important Initiatives

East Berlin TRIBUENE in German 17 Oct 80 p 7

/Interview by Hans Kramer with Prof Dr Max Schmidt, director, Institute for International Politics and Economics, East Berlin: "Military-Strategic Balance Helps Secure Peace--Nuclear War Strategists in Pentagon and NATO Gamble With Security of Nations." Some of Professor Schmidt's answers draw heavily on an article he has written for his institute's monthly journal. A translation of this article follows this interview/

/Text/ Biographic Sketch

Prof Dr Max Schmidt was born on 6 January 1932 into a working-class family. He has taught at the Edwin Hoernle civil service academy in Weimar. After completion of his studies, he held a research post at the GDR academy for political science and jurisprudence. He then graduated from the SED central committee's institute for the social sciences. After working for the SED central committee for several years, he was named director of the institue for international politics and economics and head of the research council into questions of imperialism in 1973. On a number of previous occasions Prof Schmidt has commented on topical world affairs issues in the pages of TRIBUENE.

/Question/ The resolutions and propoals put forward by the member states of the Warsaw Pact such as the declaration of last May and the foreign policy goals of our own GDR have all underscored the objective and urgent necessity for progress in military detente time and again. What are the reasons for that ?

[Answer] As everyone can see, the world situation has become a good deal more aggravated in the eighties. The results of the process of political detente which were of value to all peoples, particularly to those in Europe, in the seventies are now in danger. Instead of taking steps to relax tensions, the leading circles of the United States and of NATO are now pursuing a policy of confrontation. They are stepping up the arms race and intensifying the conceptual and material preparations for war. The conduct of the arms limitation talks is being undermined and SALT II, a treaty so very important for peace is not going into effect as a result of its ratification being blocked in the United States.

At the same time, development, production and deployment of new nuclear and "conventional" weapons of mass destruction are being forcefully pursued by NATO on the basis of its 1978 long-range program and its December 1979 resolution.

The efforts by the most aggressive forces of imperialism to do away with the existing balance of power and to establish military superiority by engaging in greatly stepped-up arms programs is casting a kind of pall over the international arena.

In view of this, continuation of detente tied to disarmament is and will remain the cardinal question for the eighties, as Erich Honecker has recently stressed once again.

[Question] You have spoken of military balance of power. What exactly is meant by this ?

[Answer] The concept of military-strategic balance of power as a pre-condition for peace is something relatively new. It was first used deliberately by the socialist countries who look upon it as one of the bases and as the guarantee for peaceful coexistence between countries with different economic systems. It involves the recognition of the fact that approximate parity in military strength between the USSR and the United States and between NATO and the Warsaw Pact has been reached as a result of a lengthy process.

And it also involves recognition of the fact that given present power relationships in the international class struggle this military-strategic balance must serve as the basis for reaching agreement on limiting, restricting and at length reducing armaments while preserving intact the security of all participants.

[Question] Could one say that there now is approximate military-strategic balance between the two power blocs ?

[Answer] Yes. The member countries of the Warsaw Pact have repeatedly pointed out that there now is military balance in Europe and in the world as a whole. This assessment is based on an analysis of all the factors which need to be taken into account, including an overall comparison of nuclear and conventional weapons systems, their number and firepower, of troop strengths and of the strategic situation.

Geographic, logistic and economic factors must also be considered. To be sure, the military power relationship is extremely difficult to assess. But one must make a realistic start on the basis of the sum total of opposing military forces. Up until recently, members of the U.S. government and of other NATO countries have more than once attested to the fact that approximate parity exists as between the USSR and the United States and the Warsaw Pact countries and NATO. This was underlined in particular by the American President on the occasion of the signing of the SALT II treaty in Vienna in June 1979. Chancellor Helmut Schmidt and other West European political leaders have also called attention to the existence of approximate parity.

[Question] What significance is there to the existence of military balance ?

[Answer] The evolution, the existence, operation and maintenance of approximate military-strategic balance between the main forces of the two different social systems in the world and of the countries allied with them is an important pre-condition for the preservation and the strengthening of peace.

This has been a decisive factor in starting on the road to political detente based on the efforts of the socialist countries and the position taken by realistic forces in the western world; a process which has been of political and economic benefit to all concerned and has opened up new vistas.

It has been a major element in thus far being able to prevent the outbreak of a third world war which is to say a war involving missiles and nuclear weapons.

It has been the principal factor for Europe, which twice has been the starting point of a world war,now experiencing the longest period of peace in this century and for the continent itself emerging as an example of peaceful coexistence between countries with different social systems.

It has provided the very basis on which successful negotiations on arms limitation and disarmament can be conducted, as SALT I and SALT II clearly demonstrate.

[Question] You have spoken of the recognition of military balance on the part of Western politicians. But what is their real attitude towards it ?

[Answer] I have already indicated by my answer to your first question that the efforts by the United States and NATO to do away with balance and to establish military superiority are the main causes for the aggravation and complication of the world situation.

[Question] What are the indications for this ?

[Answer] It cannot be overlooked that there has been a growing trend recently of members of Western governments and Western military figures --above all in the United States-- calling for making war or at least the use of military power in the service of political goals and based on superiority more practicable or efficaceous. The so-called State of the Union message by the American President in January 1980 designated the strengthening of American military power and the attainment of military superiority as the priority goal of the United States in the eighties.

[Question] In this connection, how is the American President's so-called directive 59 to be viewed ?

[Answer] This directive contains a new definition of U.S. strategy for nuclear warfare. The targets of U.S. nuclear missiles are to be varied and to be concentrated primarily on a wide range of military objectives in the USSR. In essence, this re-definition is aimed at lowering the nuclear threshold in order to carry out a preventive nuclear strike to annihilate the USSR and to be in a position to wage "limited" nuclear war.

This insane strategy is not really new. In fact, it has always gone hand-in-hand with the aims of aggressive circles in the United States wishing to confront the Soviet Union from a position of strength and superiority. But the attainment of strategic parity by the Soviet Union and the inability of the United States to carry out a devastating first strike forced American governments to recognize this parity, as evidenced among other things by the SALT agreements.

Now, the goal of overcoming military-strategic balance is openly being pursued again. In doing so, the United States are speculating on the qualitative and quantitative development of new weapons systems which are to provide a new material basis for their efforts aimed at attaining military superiority, primarily as regards a nuclear first strike capability.

They are hoping for greater accuracy, greater explosive yield and a high level of mobility for the MX and Trident missile systems among others.

/Question/ How does the NATO missile resolution of December 1979 fit in ?

/Answer/ It is absolutely correct to view this resolution in connection with U.S. nuclear strategy. In addition to the 8,000 nuclear units already positioned in Western Europe and the 3,000 nuclear delivery systems and the 1,000 delivery systems on board of warships in the Atlantic and the Mediterranean, that is to say in addition to the so-called Forward Based Systems, plans are to deploy Pershing II's and Cruise missiles with a range of 1,800 to 2,500 kilometers. Their multiple warheads, more accurate and harder to defend against, could hit different targets simultaneously. Early warning time for these medium-range missiles is reduced to about 6 minutes as opposed to 30 minutes for strategic missiles. Thus, it is not a matter of "simply modernizing" obsolete weapons, as it is said, which have the same purpose as heretofore, but of introducing strategic weapons which would reach from West European soil far into Soviet territory up to the foothills of the Urals. The NATO decision thus has the aim of bringing about a fundamental change in the European strategic situation.

/Question/ What dangers are there, in your view, in this militant concept for nuclear war ?

/Answer/ First of all, this strategy does not aim for reducing nuclear war but for materially preparing for it. As this is being done, the insane idea is being put forward that limited nuclear war can both be waged and won. But it is totally unrealistic to believe in the possibility of a limited or regional nuclear war. Any nuclear attack would inevitably lead to a direct confrontation including retaliatory strikes forthwith.

/Question/ What implications does this have for Europe ?

/Answer/ As a consequence of the NATO missile resolution, the danger of atomic conflict, particularly in Europe, has increased. The deployment of new medium-range missile systems in Western Europe within the context of the new U.S. strategy turns these countries into atomic hostages of the United States to all intents and purposes. While the United States mean to use these additional missile systems to gain substantial military advantages as regards the USSR, the nations of Western Europe for their part are called upon to bear the "nuclear risk." The arms race is further intensified.

/Question/ And what does it mean for the socialist countries ?

[Answer] In view of the acute threat, the socialist countries will have to provide the necessary measure of military security for themselves. History has proven that the socialist states, headed by the USSR, have all the means necessary to meet the efforts of the NATO countries to upset the military balance.

[Question] You are now touching on our own position. Could you be more precise ?

[Answer] Let me summarize it briefly: the socialist states do not aim for military superiority or for altering the strategic-military balance in their favor which has evolved in the course of time. This applies equally to the strategic balance that exists between the USSR and the United States and between the Warsaw Pact countries and NATO in the European area.

"Our efforts," Leonid Brezhnev has said, "are directed at not having a first or a second strike happen or, for that matter, any nuclear war at all. Our approach to this question is the following: the defense capabilities of the Soviet Union must be such that no one will dare disturb our peaceful life. Our policy does not aim at superiority in armaments but at their reduction and at a reduction of military confrontation."

This position also was part of the Warsaw Pact declaration of last May and was the basis of concrete initiatives undertaken by the socialist states at the the 35th General Assembly of the United Nations, at MBFR in Vienna and in other forums.

[Question] Which of these initiatives are most important ?

[Answer] The primary objective of all our efforts and proposals is to take further steps to reduce the danger of nuclear war. At the current U.N. General Assembly session, the USSR has countered the American nuclear war concept by submitting a list of the most urgent measures aimed at reducing the danger of war. It calls first of all for the ratification of SALT II by the United States; it calls for a start of negotiations on medium-range missiles; for tangible results at the Vienna talks and in connection with the Madrid conference and for the convocation of a conference on military detente and disarmament in Europe. There are concrete proposals on all these matters on the table.

Let me point out the special importance of the USSR initiative aimed at overcoming the impasse in medium-range nuclear weapons negotiations created by the NATO resolution of December 1979.

There is a need for negotiations on medium-range nuclear weapons in Europe-- even prior to the ratification of SALT II which, as is well known, has thus far been thwarted by the United States.

There is a need to establish an organic link between these negotiations and the problems raised by the so-called "forward based" American nuclear weapons. If any arms limitation agreements are reached in these talks, they could be taken up after SALT II has been ratified.

Erich Honecker has said that these proposals are important because "they serve to overcome the impasse in the disarmament dialogue created by NATO missile resolution adopted in Brussels."

[Question] What role do you see labor unions playing in this endeavor ?

[Answer] Ever since the Stockholm appeal in 1950 to the success of which the WFTU made a great contribution, as is well known, the unofficial organizations have grown rapidly in significance-- the way-stations being their fight against the neutron bomb over the past few years; their support for the holding of a European security conference and their active role at the U.N. special session on disarmament. The international trade union movement has had a large share in this. After all, it is the working class which plays the largest part in the worldwide efforts for peace and detente. Just the same, the recent meeting of the WFTU general council and of the WPC have both shown that more strenuous efforts must be made to combat the arms race and the danger of war.

"It is not enough to be shocked! Nor is it enough to be worried! The peoples have the power to safeguard peace which is their birthright! The time to act is now!" This Sofia appeal of the WPC is addressed to us as unionists, too.

Need for Continued Dialogue

East Berlin IPW-BERICHTE in German Vol 9 No 10, Oct 80 pp 1-9

[Analyses-Problems' feature article by Prof Dr Max Schmidt, director, Institute for International Politics and Economics, East Berlin: "Military-Strategic Balance, Political and Military Detente: U.S. Nuclear War Strategy Aims at Military Superiority-- Safeguarding Peace Requires Balance of Forces--Arms Limitation and Disarmament Versus Concept of Nuclear First Strike"]

[Text] The start of the eighties has witnessed a marked aggravation of the world situation. The results of the process of political detente which benefited all peoples, particularly those in Europe, in the seventies are now endangered. Instead of taking steps toward detente, the ruling circles of the United States and of NATO are now pursuing a policy of confrontation. The system of international relations is being strained to the utmost by the discrepancy between the readiness to agree to arms limitation and disarmament manifested in numerous declarations and treaty documents and the heightened activity on the part of the leading NATO countries which points in the opposite direction, heating up the arms race further and intensifying conceptual and material preparations for war.

The chances of success of the arms limitation negotiations are being undermined; the SALT II treaty cannot take effect, as important as it is to peace, because its ratification is being blocked in the United States and all this while the development, production and deployment of new nuclear and conventional weapons of mass destruction by NATO is proceeding apace on the basis of its long-range program of 1978 and the December resolution of 1979.

Balance of Power, Equal Security, Peaceful Coexistence

The most aggressive forces of imperialism are mounting a vastly stepped-up arms program in an attempt to do away with the existing balance of power and to achieve military superiority while refusing to supplement political detente with military detente. This has cast a kind of pall over the international arena. Safeguarding peace has thus become the cardinal issue of our time, as Erich Honecker, secretary general of the SED central committee, has said. "We must continue to work for detente in the eighties, tying it to an orientation toward disarmament."[1]

This calls for building on the foundations laid for the benefit of mankind in the seventies but which certain imperialist circles do not seem able to accept. Developments during that time had created a world situation which opened up favorable opportunities in the fight for peace. Peaceful coexistence between states with differing social systems was beginning to take concrete political and economic shape. Multilateral and bilateral treaties and agreements proved their usefulness in improving international relations. An important factor has been and still is the evolution, the existence, operation and maintenance of an approximate military-strategic balance between the main forces of the two different social systems and of the countries allied with them. This balance is an important pre-condition for preserving and strengthening peace.

It has been a decisive factor in starting on the road to political detente, based on the efforts of the socialist countries and the main realistic-minded forces in the capitalist countries: a process which has been of political and economic benefit to all concerned and has opened up new vistas.

It has been a major element in thus far being able to prevent the outbreak of a third world war, which is to say a war involving missiles and nuclear weapons.

It has been the principal reason that Europe, which twice has been the starting point of a world war, is experiencing the longest period of peace in this century and that the continent itself is emerging as an example of peaceful coexistence between countries with differing social systems.

It has provided the very basis on which successful negotiations on arms limitation and disarmament can be conducted, as SALT I and SALT II have shown.

The concept of military-strategic balance of power as a pre-condition for peace is something relatively new. It was first used deliberately by the socialist countries who look upon it both as one of the foundations and as a guarantee for peaceful coexistence between countries with differing social systems. This involves recognition of the fact that given present power relationships in the international class struggle this military-strategic balance must serve as the basis for reaching agreement on limiting, restricting and ultimately reducing armaments while preserving intact the security of all participants.

The member countries of the Warsaw Pact have repeatedly pointed out that there now exists "a military balance in Europe and in the world as a whole."[2] This assessment is based on an analysis of all the factors which need to be taken into account, including an overall comparison of nuclear and conventional weapons systems, their number and firepower, of troop strengths, of the strategic situation, of the consequences of possible surprise attacks and the effectiveness of defense installations. Geographic factors such as length and strategic location of borders, logistic and economic factors among others must also be considered.

To be sure, the military power relationship is extremely difficult to assess. To analyze it, a great number of quantitative and qualitative factors as well as global and regional ones must be taken into consideration. But, to be realistic, one must above all start out on the basis of the sum total of the military forces opposing each other. Any attempt to remove individual weapons systems or individual countries or even regions from their proper

context and to compare them will inevitably distort the picture. Overall, strategic balance is a reflection of the fact that neither side possesses or has hopes of attaining a devastating "first strike" capability.

Right up to the present, members of the U.S. government and of other NATO countries have more than once attested to the fact that approximate parity exists as between the USSR and the United States and the Warsaw Pact countries and NATO. This was underscored in particular by the American President on the occasion of the signing of the SALT II treaty in Vienna in June 1979. Chancellor Schmidt of the FRG and other West European political leaders have also called attention to the existence of approximate parity.

The existing balance of power clearly calls for another dimension in international relations: the principle of equal security which makes it incumbent upon all sides not to aim for preponderance and military superiority and, most importantly, to have this principle serve as the basis for all negotiations and agreements on arms limitation, arms reduction and disarmament.

In this sense, the principle of equal security has been upheld both in multilateral agreements such as the final document of the U.N. special session on disarmament in 1978 and in bilateral agreements such as the joint USSR-U.S. communique in Vienna in 1979 and agreements between the USSR and the FRG, the USSR and France and others.

Efforts To Attain Military Superiority Endanger Balance of Power

In view of the present international situation the question is how this fundamental aspect of peaceful coexistence is being viewed. This calls for a more exact analysis of intentions, doctrines and actions along the following lines: Are these efforts directed toward recognition of this balance, toward the reduction of the level of military confrontation and toward arms limitation based on the aforementioned principle or is this imperative being disregarded.

It cannot be overlooked that there has been a growing tendency recently of members of government and military leaders of the capitalist countries --particularly the United States-- demanding openly that war or military power as an instrument of policy based on superiority be made practicable again or be employed more efficaceously. On the occasion of a visit to the Pentagon, U.S. President Carter declared that he would see to it that the United States remains the premier military power in the world.[3] He thus clearly oriented American arms and military policy toward attainment of military superiority.

Testifying before the Senate foreign relations committee on the goals of increased U.S. and NATO arms programs, U.S. secretary of defense Harold Brown said that the purpose was to "surpass" the Warsaw Pact; to "gain a clear advantage."[4] Appearing before the armed services committee later, he asked for an increase of his military budget by saying: "We must now decide whether we intend to remain the strongest nation on earth."[5] The quest for military superiority also came up in speeches given by former secretary of state Henry Kissinger and former NATOcommanding general Alexander Haig at a conference of military experts in Brussels in early September 1979 on the subject of "NATO and the Next 30 Years." "Their statements lead to the conclusion," an FRG press report said, "that they are looking for superiority instead of approximate parity."[6]

President Carter's state of the union message of January 1980 lists concrete programs which, if carried out, would lead to a breach of approximate military parity as between the USSR and the United States and the attainment of American military superiority. The strengthening of the military power of the United States and its allies is given top priority in the eighties. In the current fiscal year alone, U.S. military expenditures will increase by $20 billion and by the middle of the eighties the U.S. military budget is to be more than $200 billion.

Special emphasis is being placed on strengthening the nuclear missile arsenal. Development and production of qualitatively newer strategic offensive weapons systems, among them the MX missiles, fixed-wing missiles and Trident missiles, are proceeding. A start has been made on the development of an interventionist "rapid deployment force" together with a special fleet of floating naval bases and an air transport fleet capable of transporting large-size units to the farthest reaches of the earth.

In political science communities in the capitalist countries voices justifying this policy of military power and the deployment of it are becoming louder. R Kennedy of the U.S. Army College's Strategic Studies Institute calls the ability to resort to force a pre-condition for successful negotiation and defines the function of military power as being "its ability to threaten and, if necessary, to resort to military power so as to force a preferred point of view upon the world order."[7] So much is clear: The quest of the United States for military superiority is to serve the goal of "forcing the point of view preferred" by U.S. imperialism upon the world order.

The heightened arms buildup by the leading NATO power is based on designs for worldwide expansion and not on U.S. security interests. Thus the former American diplomat Arthur M. Cox wrote as long as 5 years ago: "Brookings Institute analysts believe the defense budget could be cut in half, if our only object were to defend the territory of the United States."[8] In the meantime, U.S. arms expenditures have escalated to such an extent that the discrepancy between security needs and expansionist designs has widened even more. The United States is the only country which disposes of a worldwide system of military bases in 114 countries.[9]

'New' U.S. Nuclear War Strategy

In this connection the most recent decision of the President of the United States relating to U.S. nuclear strategy must be viewed with considerable alarm. Jimmy Carter signed "directive 59" which calls for varying the targets of the strategic nuclear missiles. Essentially, this change is designed to carry out the first strike against military objectives in the Soviet Union, to lower the nuclear threshold so as to be able to wage a limited nuclear war.

This concept of a limited strategic nuclear war against the USSR is not new. It was developed as long ago as 1974 by the then U.S. defense secretary Schlesinger and its origins, in fact, go back even further than that. When all is said and done, it always conformed to the designs of the forces opposed to detente which mean to confront the Soviet Union from a position of strength and superiority.[10]

The attainment of strategic parity by the Soviet Union and the inability of the United States to carry out a decisive and devastating strike forced the various U.S. governments to recognise this parity situation. This was manifested in the documents relating to the limitation of strategic offensive weapons and missile systems of 1972, in the treaty on the prevention of nuclear war of 1973 as well as in later protocols.

But there always were powerful forces among the ruling circles of the United States which were unwilling to accept strategic parity. They were constantly looking for military superiority which they define as the capability of carrying out a devastating first strike with superior weapons systems. The quest to attain such a first strike capability has never been relinquished by any U.S. government. Their approach to arms control and disarmament agreements has been and always is tied to the option of leaving the way open for once again attaining military superiority. This was particularly apparent in the debate on SALT II in the United States.[11]

Contrary to the official pronouncements of the American government that it is prepared to maintain parity vis-a-vis the USSR and is cognisant of the danger of a violation of the principle, there are renewed attempts now to aim at overcoming the military-strategic balance both materially and conceptually. The United States is basing its efforts on the qualitative and quantitative development of new weapons systems designed to provide a new material foundation for its quest after military superiority, primarily in the sense of attaining a nuclear first strike capability. There are three aspects relating to the qualitative factors upon which they are basing their hopes.

The first factor is the accelerated improvement of the accuracy of the nuclear missile systems; secondly, they are trying to increase the strength of the warheads and thirdly, they are trying to perfect so-called invulnerability or at least to make it more difficult to defend against U.S. weapons systems.

In this way they are attempting to develop the capability for a "disarming" first strike. A start was made as long ago as late 1977 when 300 Minuteman III missiles were equipped with the MK-12a nuclear warhead which is twice as strong and as accurate as its predecessor. But with the signing of directive 59 the following new weapons systems are coming into play.

First, there is MX, the intercontinental mobile ballistic system of land-based nuclear missiles. 200 of these have been included in the U.S. arsenal. Based on statements of U.S. experts, these missiles have a destructive capability 20 times as great as that of Minuteman III due to their greater accuracy and strength; they are mobile and therefore considered invulnerable.

Secondly, there is the development and deployment of sea-based Trident II missiles with individually controllable and maneuverable warheads. Each U.S. atomic submarine, equipped with 24 of these missiles, is capable of annihilating at least 200 fortified military targets. A report prepared by the U.S. arms control and disarmament agency refers to these missiles as first strike weapons with a significant potential for destroying priority targets.

Thirdly, there is the development of new types of aircraft and missiles which are said to be insensitive or marginally sensitive to radar. According to U.S. defense secretary Brown, they are already in the testing stage and should, he says, alter the military balance considerably. Clearly, the new assessment of nuclear strategy undertaken by directive 59 is based in large part on these systems.

Fourthly , in the light of the President's directive, there is a need to assess the decision of 12 December 1979 relating to the development and deployment of U.S. medium-range nuclear missile systems (Pershing II and Cruise) in Western Europe. In view of strategic parity between the USSR and the United States, U.S. political leaders and military planners, in seeking renewed superiority, are concentrating not only on the development of new strategic weapons systems but also on regional aspects, which is to say a shift of "regional balnces of power" in their favor. In this, they assign highest priority to Europe. It is considered a particularly important arena of military confrontation with the Soviet Union and the member states of the Warsaw Pact.

The so-called Schlesinger report set the course in this direction in 1975. In positing alleged Soviet aggressive designs against Western Europe and the deterrent function of NATO, the report said that "the threat of mutual annihilation narrows the range in which enemy actions can be deterred by strategic forces and places greater emphasis on deterrence by medium-range missiles and conventional forces."[12]

As long ago as 1975 priority was thus given to increasing the NATO medium-range missile arsenal as part of a long-range strategic program whose point of departure was actual military-strategic balance and by no means Soviet military superiority. In the meantime, the present U.S. defense secretary Harold Brown has come out with much clearer and more comprehensive language. In his report to Congress on the proposed military budget for fiscal year 1980/81, he said: "In our view, NATO needs a strategic 'triad' of its own which is different from ours...It must dispose of nuclear-strategic forces, tactical nuclear weapons and non-nuclear forces."[13]

In practical terms, this comes down to dual military-strategic superiority. According to this scheme, the nuclear-strategic forces of the USSR would be opposed both by those of the United States and those of NATO. The first line would be occupied by the "Euro-strategic" weapons systems pursuant to the NATO resolution of December 1979 whereas the new weapons systems Pershing II and Cruise are clearly intended to provide a first strike capability. The 1975 Schlesinger report which "justified" the stronger emphasis on medium-range missiles had already provided in no uncertain terms for the nuclear first strike option. Although "clearly limited, the attack should be carried out with sufficient force and decisiveness in order effectively to alter the conceptions of the Warsaw Pact leaders and to create conditions favorable to negotiations."[14]

Now this was by no means a threatening gesture of a mere tactical nature for as M. Kahler of Princeton University points out there are indeed forces active in the United States today which hold the principle of "assured mutual annihilation" to be obsolete and which are therefore coming out in favor of making nuclear weapons "applicable."[15] And they are not restricted to the United States. Commenting on directive 59, FRG military analyst A Weinstein, known for his outspoken support for the aggressive NATO strategy, wrote on 6 September 1980: "It is no longer true that there can be no victors in a nuclear war. It would depend on what kind of nuclear war is waged. Whoever carries out a first strike with precision weapons and in so doing destroys the offensive weapons of the enemy has a chance of winning."[16]

NATO Missile Resolution Aims at Changing Military Balance

What significance does the NATO resolution of December 1979 have with respect to the military power relationship ? To add to the 8,000 nuclear units already positioned in Western Europe and the 1,000 delivery systems on board of warships in the Atlantic and the Mediterranean, it has been decided to produce qualitatively new American nuclear weapons and to deploy them in Western Europe, namely Pershing II missiles as well as fixed-wing missiles (the so-called Cruise missiles) with a range of 1,800 to 2,500 kilometers and an in-flight time of mere minutes. Their multiple warheads, being more accurate and harder to defend against, could hit different targets simultaneously. Early warning time would be reduced from 30 to 4 to 6 minutes.

Thus, it is not a matter of "simply modernising" obsolete weapons, as it is said, which have the same purpose as heretofore, but of introducing strategic weapons which would reach from West European soil far into Soviet territory up to the foothills of the Urals. The NATO decision thus has the aim of bringing about a fundamental change in the strategic situation in Europe and at the same time undermines the agreements reached in the SALT II treaty. Bundeswehr major general (ret) G Bastian along with many other Western politicians and analysts considers this to be a "new situation" for the Soviet Union "in that the USSR does not have equal opportunities, namely to pose a nuclear threat to the United States with medium-range weapons."[17] So it may be said that the United States has set its course on developing a first strike capability in the European theater as well.

The NATO position relating to the proposed stationing of new medium-range nuclear missiles in Europe is being justified above all with the alleged need for "modernisation." This position does not conform to reality-- either historically, politically or militarily. As to the historical aspect, it may be recalled that NATO's original tactical decision to station new American missiles

does not date from December 1979 but from the fall of 1977 when it was reached at the NATO nuclear planning group meeting in Bari. The official report of the U.S. Arms Control and Disarmament Agency for FY 1980 states that the budget decisions for the development of the Pershing II missile were reached as long ago as 1974.[18] The Soviet missiles, however, which have repeatedly been used as ex post facto "justification" were an unknown quantity until 1975 by the United States' own admission. And the funds for the development of the fixed-wing missiles were decided upon even earlier, in 1972. Furthermore, it is worth recalling the previously mentioned American long-range plans for the attainment of military superiority which assign a labor-sharing role to the medium-range missiles.

As for the political aspect, long before the new medium-range nuclear systems of the United States and of NATO were decided upon and prior to the modernization of its own arsenal, the USSR proposed inclusion of medium-range weapons in the SALT negotiations. But, as the imperialist camp admits, these weapons were excluded by the United States.[19] Similarly, the Soviet proposals of 1979 for negotiations on the medium-range arsenal were simply brushed aside.

As for the military aspect, it should be pointed out that there is approximate parity in the medium-range nuclear weapons field, too, if not only similarity of available means but similarity of actual effectiveness are considered.

To justify the "modernisation" lie, all sorts of calculations were being offered in the NATO countries, which were self-serving and exceeded the bounds of exaggeration. A particularly revealing example for this type of manipulation is a study commissioned by a group of CDU Bundestag deputies. According to the study, "Soviet superiority over NATO in short-range missiles stands at 4.5:1."[20] But Hamburg peace researcher Dieter S Lutz has taken a close look at the calculations on which this particular manipulation is based. He has found "that there is no way in which NATO military inferiority can be deduced in the TNF field. On the contrary, it cannot be ruled out that the Warsaw Pact may have to counter quantitative and qualitative improvements in the NATO arsenal by adopting modernisation measures of its own."[21]

Comparative figures worked out by Lutz and based on total NATO and Warsaw Pact strength add up to a ratio of 1,622:1,637 systems. Now this reflects approximate parity without a doubt. In this calculation, the total number of weapons systems is taken into account as well as their differing qualitative criteria. Justifiably, the calculations are also based on the need to include U.S. and NATO systems frequently excluded by the bourgeois camp such as American equipped with Poseidon missiles operating in the Atlantic and the

Mediterranean under SACEUR; carrier-based aircraft in the same area, and all NATO with a range of more than 1,500 kilometers. Also included are the nuclear weapons systems of France and Great Britain.

As long as the aforementioned U.S. Forward Based systems which are capable of reaching the Soviet Union and against which the land-based Soviet missile arsenal constitutes a reply are excluded, there is no comparing and no negotiating about medium-range weapons systems. This is confirmed --unintentionally, it may be assumed-- in a report by the chairman of the U.S. Joint Chiefs of Staff, which states: "The U.S. contribution to LRTNF consists of forward-based F-111 and A-6 aircraft as well as a significant number of Poseidon RV's, all assigned to SACEUR."[22]

There are also major differences with regard to their strategic mission between the Soviet SS-20's and the proposed Pershing II's and the Cruise missiles which should notbe left out of consideration. The SS-20's are a replacement with no increase in range for the SS-4's and SS-5's which had already been in use for more than 10 years.

The deputy director of the London International Institute for Strategic Studies, G Treverton, confirmed this fact which has been pointed out by the Soviet Union on a number of occasions, stating the SS-20 poses "no qualitatively new threat" as compared to the obsolete delivery systems.[23] And Stockholm-based SIPRI in its latest yearbook also states that "if the existing missiles are replaced piecemeal by SS-20's, this does not introduce a quantitatively new threat." As for designating the Pershing II and Cruise missiles as "modernization," SIPRI calls that an "understatement"pointing to "qualitatively new capabilities" NATO could gain at the expense of the Warsaw Pact organisation.

The number of medium-range missiles has not been increased in the European part of the USSR during the past 10 years, nor has the number of corresponding aircraft. Furthermore, the Soviet Union has stationed no such weapons on the territory of its allies. As a matter of fact, the number of medium-range missile launch pads and their nuclear warhead strength were decreased somewhat as was the number of medium-range bombers. The ministerial meeting of the NATO nuclear planning group in The Hague in November 1979 itself confirmed the fact that "the total number of Soviet missile launching sites targeted on NATO territory in Europe has been reduced somewhat in recent years."[24]

In a speech before the Brookings Institute in February 1980, defense secretary Harold Brown also acknowledged the fact that the USSR did not increase the number of its medium-range weapons and warheads in the seventies, but in fact decreased them.[25]

Thus, the NATO decision to develop, produce and station new medium-range nuclear systems in Western Europe is not the result of military superiority or a threat on the part of the Warsaw Pact states but based on the desire to attain military superiority and to abrogate the principle of equal security as the basis of mutual relations and negotiations.

A Deadly Scheme

The entire scheme of the United States and of NATO to gain superiority with the help of new weapons systems is highly dangerous and a threat to peace:

1. The danger of a general war involving missiles and nuclear weapons is not reduced but heightened; above all because there is an erroneous assumption of being able to wage and to win a limited nuclear war. It is a view that completely disregards reality that a localized nuclear war could be waged. Any nuclear attack would escalate into a direct confrontation in short order and involve retaliatory strikes. The 30th Pugwash conference of noted world scientists in late August 1980 rightly called for steps to counter this madness. M Kaplan of the United States, the secretary general of the international Pugwash movement said in conclusion: "Perhaps the worst thing that has happened is the increasing promotion and public acceptance of the idea that limited nuclear wars could be fought without the risk of nuclear escalation, that nuclear wars could be survived and won."[26]

2. The danger of nuclear conflict is heightened as a result of attempts by the United States and NATO to develop a first strike capability which is to say --in connection with directive 59-- above all in Europe. The deployment of new medium-range systems in Western Europe turns these countries into nuclear hostages of the United States to all intents and purposes. Whereas the United States are aiming for a considerable military advantage vis-a-vis the Soviet Union by adding these missile systems, the West European countries are called upon to bear the "nuclear risk." This has not only led to considerable uneasiness among the population but also to suspicion and anxiety among realistically thinking West European politicians.

Contrary to the U.S. position, official and unofficial views are being voiced in some of the smaller member states of NATO which oppose the new U.S. strategy aimed at lowering the nuclear threshold. This is true for example of the two largest political parties in the Netherlands[27] and equally of the retired FRG general Baudissin who now heads the Hamburg Institute for Peace Research and Security Policy and who warns of the dangerous consequences this U.S. nuclear war strategy would have.[28] There is a growing realization that the danger of military conflict in Europe and

for its population cannot be "escalated out of existence" by introducing new weapons systems but that military detente and arms reduction are needed.

3. The arms race is being stepped up. There are new rounds being started which forces the socialist states to take the necessary steps to safeguard their military security in view of the acute threat. History proves that the socialist states have the capability to match any new weapons technology introduced by NATO with corresponding new weapons of their own which are necessary for their defense. But it is a new round in the arms race with its very grave consequences that the socialist states would like to prevent.

It should be noted that a new round in the arms race does not in any sense signify a mere numerical enlargement of "somewhat modernized" weapons systems. Based on this erroneous thesis, some bourgeois journalists have come to the "reassuring" conclusion that military balance is bound to restore itself in the end. This would lead to a restoration of the status quo guaranteeing world peace once more. If one group of states were to add more arms to its side of the scales, the "international scales" would balance out again as soon as the other group of states adds an equal number of "weights" to its side.

The metaphor of the scales is antiquated and obviously deficient because of the mechanistic symbolism involved, even if it does have a certain descriptive value. At any rate, if it is used, one must not overlook a most important fact. Any scales can be weighed down up to a point. But if it is overloaded, the whole system collapses.

Any sober and objective assessment of the military-strategic situation in the world and above all in Europe must lay stress on the conclusion that armaments both in terms of quantity and quality are now dangerously close to the upper limit of the loading capacity of the military balance system. There is a fundamental threat to strategic stability in any new round of the arms race, particularly in the development, production and deployment of weapons of mass destruction and delivery systems with materially new capabilities. More and more realistically thinking politicians are coming to realize this. The long-time head of ACDA, Paul Warnke, for example, wrote: "The Russians are capable of warding off any threat to strategic equality just as we are able to forestall any attempt of theirs to attain superiority. The result of any stepped-up competition will be a situation comparable to the present but characterized by a higher level of potential destruction and more unsettled political conditions...Today, the best alternative which offers a guarantee against nuclear war is the

conclusion of agreements on strategic arms control conducive to reducing tensions and to paving the way to comprehensive and more effective disarmament in the future."[29]

4. An arms race which aims at the attainment of military superiority undermines the principle of equality of states in the system of international relations. The quest for hegemony is fostered; a policy of strength and the attempt to apply military pressure and to resort to blackmail to turn negotiations into dictates gains favor. There would doubtless be an increase in tensions and in suspicion between groups of states not only in international relations including those in the economic field. Clearly, this would also impede the work of all existing and projected bodies dealing with arms control and disarmament and impair the basis for negotiation.

5. Finally, there is a need to point to the many economic and social consequences of such a process for all states whether directly or indirectly concerned. Although these consequences are not discussed here, there is no doubt but that they would be extremely grave.

Arms Limitation and Disarmament Based on Equal Security

Despite all presently existing tensions and difficulties in world affairs, the socialist states believe that the process of detente and the results attained thus far must continue to have priority in international relations. They are in favor of constructive steps such as to counter further hardening of the international and the European situation.

The socialist states aspire neither to military superiority nor to a shift of the military balance which has historically evolved in their favor. This applies both to the strategic balance between the USSR and the United States and between the Warsaw Pact and NATO in the European area. It was already in 1977 that Leonid Breshnev called the allegations according to which the Soviet Union was aspiring to nuclear superiority in order to carry out a first strike "nonsensical and totally unfounded," adding that "our efforts are in fact aimed at preventing both a first strike and a second strike and, for that matter, nuclear war itself."[30]

In May 1980, the Warsaw Pact countries renewed their pledge of never developing a nuclear first strike capability and of never arrogating to themselves any control over "spheres of influence" or international transport routes.[31] Their whole policy aims at eliminating the military factor. But as long as significant progress in the direction of general and total disarmament cannot be reached, the military factor continues to be important. That

is why the preservation of the military balance is one of the fundamentals of peaceful coexistence between states with differing social systems. But it is not only a military factor but also a pre-condition for practical measures aimed at arms limitation and disarmament.

The central goal of the foreign and security policy of the Warsaw Pact countries continues to be a reduction in the level of military confrontation on the basis of reciprocal reduction of forces and armaments. Their policy continues to be based on the principle of equal security, respect for the legitimate security interests of other states and readiness to enter negotiations about all types of weapons. The only condition they attach to all their proposals for arms limitation and disarmament is unequivocal and effective respect for the principle of equal security for both sides.

This position is also being supported by leading bourgeois experts. G Kristiakowski, for example, a former scientific adviser of the President of the United States and a long-time member of the top staff at the Los Alamos atomic center, wrote: "To reach agreement (on arms limitation-ed) we must unequivocally grant the Soviet Union equal status and take her legitimate security needs into consideration."[32]

The Warsaw Pact countries consider the preservation of approximate parity of forces an important stabilising factor in world affairs. For this reason, their proposals have been and still are aimed at maintaining approximate military balance at a level to be gradually lowered with a view to reaching effective and mutually acceptable reductions in arms expenditures.

The Warsaw Pact countries are making numerous efforts to thwart any attempt aimed at disturbing the military-strategic balance and achieving one-sided military superiority. Now that the United States and other NATO members have set their sights on a new, stepped-up arms race, the Warsaw Pact countries have no other choice to adopt measures to increase their defense preparedness in the sense of preserving approximate military parity. These are measures that pose no threat to the security of any other country. But the socialist states cannot accept any disturbance of the military-strategic balance because this would endanger their security and threaten world peace.

The communique of the meeting of the political consultative committee of the Warsaw Pact countries in May of this year spells out the main points of this coordinated socialist foreign policy which is in the interest of their own security needs and those of the world as a whole:

First: Agreement on the principle that no state or group of states in Europe may after a certain date increase the numerical strength of its armed forces in the area designated by the Helsinki Final Act. This is also how the most recent initiative of the socialist participants at the Vienna negotiations is to be understood. The deadlock at these negotiations could thus be broken and first results could be achieved, if the proposal were accepted to withdraw 20,000 military personnel of the USSR and 13,000 of the United States during the first stage of troop reductions as well as to impose a collective "freeze" on troop levels during the "intervals" between the reduction stages.

Second: Strict adherence to all terms of the Helsinki Final Act, above all to the basic principles all participants have pledged to uphold-- such as the renuncication of force or the threat to use force; the inviolability of national frontiers; the peaceful settlement of disputes; the non-interference in internal affairs; the fulfillment in good faith of obligations under international law.

Third: Intensive bilateral and multilateral exchanges of opinion in order to structure the Madrid conference in such a way that practical steps aimed at comprehensive implementation of the Final Act can be agreed upon.

Fourth: Stepped-up preparations for a conference on military detente and disarmament in Europe with the aim of reaching practical decisions in Madrid on the agenda, date, location and mode of operation of the conference and of concentrating the work during the initial phase on confidence-building measures.

Fifth: Ratification of the SALT II treaty and speedy conclusion of negotiations going on at present and/or broken off such as the talks on banning nuclear tests, radiological and chemical weapons and on the non-use of nuclear weapons against non-nuclear nations.

Sixth: Immediate start of constructive negotiations on such issues as a world treaty on the non-application of force, a ban on the production of nuclear weapons and a ban on the development of new types and systems of weapons of mass destruction.

Seventh: Discussions on the limitation and reduction of military presence and military activities in the Atlantic, in the Indian Ocean, the Pacific, the Mediterranean and in the Persian Gulf.[53]

The primary object of all these efforts and proposals is to make further progress in reducing the danger of nuclear war. In addition to the ratification of SALT II, this calls for reopening the way to negotiations on medium-range missiles. As is well known, these

negotiations were blocked as a result of the refusal of the Soviet offer of 6 October 1979 and the NATO resolution on medium-range missiles of December 1979.

New Soviet Proposals

The newest initiative of the Soviet leadership calling for immediate consultations on the best approaches to solve the medium-range nuclear missile issue which was submitted both to the chancellor of the FRG on the occasion of his visit to Moscow in June 1980 and to the U.S. leadership is therefore of extraordinary, fundamental and topical importance. What are its main points ?

Its purpose is to start discussions and preliminary negotiations as soon as possible on medium-range nuclear weapons in Europe--even prior to ratification of the SALT II treaty which, as is known, has been blocked by the destructive position taken by the United States.

The point is to conduct these talks "within the organic context" of the issue of the so-called forward based American nuclear weapons, including, as mentioned previously, the F-111 and Phantom combat aircraft stationed in Great Britain as well as American nuclear submarines assigned to NATO, particularly those on patrol in the Mediterranean.

Arms limitation agreements reached in these talks, if any, could be taken up which is to say realized following ratification of SALT II.

Such talks could commence without any pre-conditions whatsoever.

Erich Honecker, secretary-general of the SED central committee, has called these proposals "a means of breaking the impasse in the disarmament dialogue caused by the NATO missile resolution in Brussels."[34] Evidence that the proposals are considered to be meaningful is reflected in positive statements on some aspects of them in various European NATO countries. Thus, FRG chancellor Helmut Schmidt said he thought the inclusion of FBS in such consultations to be "quite logical," adding that he could "appreciate the Soviet position with respect to SALT II."[35] SPD disarmament expert Pawelczyk made a point of stressing that the Soviet proposal offers a way of gaining time and "one possibility of preventing an arms race in Europe in the medium-range nuclear systems field."[36]

Addressing letters to Western heads of state and government in August, the secretary-general of the CPSU central committee, Leonid Brezhnev, made new efforts to get the talks started. In a joint press conference, the U.S. and FRG foreign ministers reacted --at least indirectly-- by announcing their readiness to enter preliminary talks soon.[37]

But in this case, too, the idea is to take concrete steps without delay. And, one cannot help noting that a kind of rejection movement against the USSR proposals is already beginning to form in some of the NATO countries. There are demands, for example, not to include FBS in the talks, but only medium-range missiles. But even NATO military experts do not deny --as we have already shown-- that the stationing of Soviet medium-range missiles in European Russia was meant as and still constitutes a reply to the so-called FBS which in effect fulfill the function of medium-range nuclear missiles. In the final analysis, the issue is the entire range of weapons which fulfill the same or a similar function-- unless one is making an attempt arbritarily to alter the present approximate military balance in one's own favor.

Pessimistic estimates are also being given according to which it would be extremely difficult to conduct such talks and negotiations because of the subject matter involved. It may even take years to agree on a mutually acceptable definition of the matter at issue, it is said.

But: the subject matter treated by SALT I and SALT II also was extremely varied, particularly with respect to the comparability of types of weapons, their location and range and their destructive capabilities, etc. Nonetheless, results were achieved conforming to well-perceived bilateral interests. The decisive aspect is mutual good will which in the end contributes greatly to mutual trust. The peoples impatiently expect and yearn for negotiations. The apparent and totally unfounded hesitancy in the guise of the alleged need to give careful "study" to the USSR proposal gives rise to suspicions that the object is to gain time in order to pursue goals and arms measures of one's own and to create accomplished facts of a most dangerous nature.

Today's world is one of heightened tensions. The situation is complicated. It demands the highest degree of political readiness to to work toward and to conduct a dialogue about issues in dispute and at the same time to avoid anything that might contribute to aggravating the situation. A shift toward military detente in the eighties is possible, if the negotiations are based on the existing approximate strategic balance and the principle of equal security for all sides.

WEST GERMAN ANALYSIS OF GDR COMBINE SYSTEM DEVELOPMENT (II)

Cologne DEUTSCHLAND ARCHIV in German Vol 13 No 10, Oct 80 signed to press 26 Sep 80 pp 1046-1062

[Part II of 'Analyses and Reports' feature article by Kurt Erdmann and Manfred Melzer: "The New Combine Decree in the GDR — Possibilities and Limits of the Productivity Stimuli of the Newly-Formed Combines." A translation of Part I of this article is published in JPRS 76865, 24 Nov 80, No 2065 of this series, pp 31-52. Translations of six below-cited articles from the following two East Berlin journals are published under quoted headings in JPRS issues of this series as indicated: Three items from EINHEIT: Footnote 1 — Fritz Haberland, Wolfgang Salecker, "Combine Managers' Tasks, Improved Production Methods Discussed," 76104, 24 Jul 80, No 2026, pp 34-76; footnote 45 — Horst Martens, "Petrochemical Combine Expansion, Rationalization Discussed," 76459, 19 Sep 80, No 2043, pp 43-45; and footnote 62 — Gerd Friedrich, Klaus Kroemke, "Combine System's Development, Future Tasks Analyzed," 75132, 14 Feb 80, No 1980, pp 15-26. Three items from WIRTSCHAFTSWISSENSCHAFT: Footnote 16 — Rudolf Gerisch, Willy Hofmann, "Effective Combine Management Seen Vital to Economic Success," 73083, 26 Mar 79, No 1872, pp 13-39; footnote 31 — Ingo Wolf, "Combine Responsibilities for Construction Deadlines Outlined," 74274, 6 Dec 79, No 1961, pp 33-48; and footnote 82 — Gerd Friedrich, "Combine, Enterprise Management and Planning Reviewed," 76335, 29 Aug 80, No 2038, pp 7-32. Also available is a translation of an earlier DEUTSCHLAND ARCHIV article by Kurt Erdmann, cited in footnote 85, published under the heading, "Problems Cited in Industrial Design Development," in JPRS 74271, 27 Sep 79, No 1937 of this series, pp 24-36]

[Text] Part I of this analysis (published in issue No 9, 1980, pp 929-942) initially discussed the new combine decree, both from the standpoint of earlier legal provisions regarding enterprise organization as well as follow-up regulations issued in the interim. This was supplemented by a description of the benefits which the economic leadership anticipates from the combines in remedying at least some of the existing functional weaknesses and reducing the problems that have arisen as a result of foreign economic strains. Next came an analysis of changes in the economic management system that came about once the VVB's [associations of state enterprises] were abolished and integrative enterprise mergers (combines) were established. Another important point was the limited expansion of the authority of combine managements to make decisions.

Part II of this study concentrates on industrial management problems affecting internal combine organization. Solution of these problems will ultimately determine whether the — so urgently needed — general improvements in productivity can or cannot be achieved with the combines.

IV. Priorities and Problems of Managerial Intensification Efforts in the Combine

1. Industrial Management Objectives

The industrial management sector is the main starting point for the active mobilization of productivity in the combine reorganization process. The GDR economic leadership's expectations resulting from a revision of the internal organizational structure as well as from crucial process-related changes are directed toward the potential ability of the new combines to make a qualitative leap, as it were, to a higher level of productivity by coordinating specific actions aimed at the intensive mobilization of all industrial activities. Among the justifications offered is that "previous development trends in the growth of production, in the development of productivity, can no longer be realized with the same means" as before; rather, "qualitative changes..." are "necessary."[1] Priorities in the call for a critical review and rationalization of the combines' own potential are increased efficiency and the managerial result as measured by success (plan fulfillment, profits, cost minimization) — quite apart from the axiomatic fulfillment and overfulfillment of national economic plan quotas.

One of the GDR's leading economists, Koziolek, therefore characterized the industrial importance of the combines in these words in 1979: "Most of the national economy's intensification processes intersect in combine and enterprise reproduction and are ultimately realized there."[2]

The possibilities for internal enterprise rationalization and the problems involved have consequently been discussed intensively at a number of economic and political conferences in recent years, but seldom has there been any clear result.

The special importance ascribed by the economic leadership to establishing a new "internal containment" of the entire industrial process in the combine[3] can be seen in the fact that this demand was included in Art 1 of the new combine decree,[4] although toned down somewhat ("largely contained reproduction process"). This cautious wording is doubtless occasioned by the negative practical experiences in realizing the "self-contained system of economic levers" as the core of the reform phase of the New Economic System in 1963. Probably, however, the ideas at that time on achieving "internal containment" were behind the present-day planning. The effort to arrive at a contained economic system was not successful then. Today the hope is for at least a largely "consistent combine system." This in turn may be equated with a general revaluation of industrial management problems.

One of the most important points on the combine reorganization agenda is the best possible adaptation of combine structural organization to the specific conditions that exist in each case. Guenter Mittag stressed this at the combine conference in 1978: "So one should do what is necessary in the area of organization, but I should like to warn expressly against treating formation of the new combines in just one way, as a problem of structure and organization."[5]

A number of measures, procedures and demands can be listed among the efforts to arrive at an improved combination of factors and a more efficient structuring of industrial spheres of activity in the combine. Only a few main markers — with no claim to completeness — are featured here, set against the backdrop of an extremely broad catalog of industrial management tasks found in the "joint directive" of the party and government on drafting the 1981 National Economic Plan,[6] and also borrowing from the four essential industrial production factors found in Western business administration theory:[7]

(1) Dispositive factor (management and organization as essential intensification factors, for example);

(2) Capital or working capital factor (including the "effectiveness of capital assets"[8]);

(3) Labor factor (including the use of industrial labor resources and especially the "saving of human labor"[9]);

(4) Materials factor (including the "efficient use of energy, raw materials and material"[10]).

Another key area in the internal sector is the question of the extent of relative autonomy on the part of the combine enterprises, thus also of the principle of economic accounting — as an essential "method of systematic management..., in order to carry out in the enterprises the most effective means of plan fulfillment while making the most efficient use of resources."[11] With a few exceptions, a discussion of further industrial management details in this context must be omitted.

2. Management and Internal Combine Organization

Special importance is ascribed to the formative force of the dispositive factor in the phase of combine reorganizations in particular. Four basic types of combines are differentiated in the GDR literature:[12]

(1) Management by a central combine management of a combine having only one enterprise (Leuna Works, for example);

(2) Management by way of an independent management apparatus of a combine having several enterprises (VEB Carl Zeiss Jena Combine, for example);

(3) Management by way of a main enterprise of a combine having several enterprises; this management guides the entire combine simultaneously (for example, the Mansfeld Combine, the Bitterfeld Chemical Combine, the IFA Passenger Vehicle Combine);

(4) Management by way of control enterprises for various product groups for combines having several enterprises (for example, the Microelectronics Combine, the Deko Combine, the Radio and Television Combine).

In cases 1 and 2 it is critical to note that the tighter internal structure created with centralized combine management also involves greater dangers and risks: lines of planning and decisionmaking that are too long; reaction times that are too lengthy in the case of coordination processes; thus the possibility of decisions that are too far removed from practical application. To be sure, the top level of the combine could be organized efficiently so that it would function more as a controlling and supervisory organ — along the lines of a holding company — and would have only minimal opportunities to influence enterprise operations. But this would be totally at variance with the intention of using the combine leaders to achieve state goals.

In the case of combine formation with management by a main enterprise (case 3) — for us this is approximately comparable to a takeover of competitors by the market leader — set against the advantage of a centralization of a centralization of production processes and thus a lower-cost mass production (in the case of turning over small-lot production to small-scale enterprises and other specialization and centralization effects) are three not insignificant disadvantages: It is difficult to select the most suitable main enterprise and the general director from among the enterprises to be merged; the main enterprise selected does not have to be the best economically and could thus become a false standard for the others as a result of its leading position; finally, in order to increase its efficiency the main enterprise could divert from others to itself parts of the program that are beneficial, or it could assign unfavorable parts to other enterprises.

Particularly in the case of combine formation with control sectors (case 4) — which has been instituted above all in consumer-oriented sectors — the trend toward large-scale enterprise forms for product groups could produce distinct disadvantages for consumers despite centralized planning: Long-established, finely tuned structures could be destroyed, products dropped, variety further reduced and the varied marketing channels of former single enterprises sacrificed. Moreover, multiple chains of command and accompanying conflicts of interest by enterprises in the combine system are possible with this combine form in particular.

Internal organization can form only the outer framework in the establishment of more productive economic units. Needed above all is a better quality of management work itself in order to do justice to the many and varied responsibilities — conserving raw materials and setting a course for new procedures, for example.[13] The necessity[14] here is to view problems less from a situation-related and more from a process-related standpoint, to perceive to a greater extent elements that can be changed and influenced and not to overestimate outside influences. In addition, a GDR study reveals, following a survey of managerial personnel, that there are still many different things that must be done to improve management, especially because of the "lack of organization" that is still frequently in evidence and because there are still "too many short-notice directives" that have to be issued.[15] At lower levels of management there is an inhibitive effect in that decisionmaking powers are quite limited and only inadequate participation in the preparation of decisions is allowed.

It is basically within the purview of the combine's "management organization" to develop a tight and less bureaucratic management system with shorter lines of decisionmaking — one of the main arguments for the reorganization. Moreover, high priority is being accorded the so-called "expertise principle,"[16] thus a qualified

team of leaders for the combine. Greater emphasis than in previous regulations is found in Art 3, par 5, of the new combine decree with the demand that management is "to be organized comprehensibly" and in "the most efficient manner."[17] For instance, the "expertise principle" is grounded in Art 24, par 3, with the term (management) "close to production."[18]

A general objective here, and one that must be assessed positively, is that management would be drawing closer to production, production will possibly be structured better and fewer instances of intersectoral coordination will be necessary on the level of the economy as a whole. While three of the aforementioned organization models of a combine are included in the combine decree (Art 26), this new decree makes no provision for the former regulation covering combines in the form of the large-scale enterprise with legally dependent enterprise branches (case 1); the VEB decree dating from 1973 had made specific provision for such enterprises (Art 24, par 1).[19] It remains to be seen whether and to what extent combines of this systemic type dating from 1968 will undergo a possible conversion in the future. Even considering the few problems cited here, it becomes apparent that the completed reorganizations have caused numerous internal combine management as well as planning problems that are new and in part quite complicated, problems that cannot be solved in a day. It should therefore be kept in mind that the internal management buildup in the combines is still in full swing and that much experimenting is still being done in this very area.

Good "manageability of the overall organism"[20] depends just as much upon questions of allocating management responsibilities and delegating duties (for instance, with staffs, the position of state commissioners, functions of SED party organizations and other "social management organs"[21]) as it does upon the solution of pressing problems involving the industrial information system[22] and the use of EDP. But also important is the intelligent application of both mathematical and cybernetic models[23] and methods by combine management. The "collective advisory organs" mentioned in the combine decree (Art 5, par 4) are intentionally not described further by order of the "Legal Department, Council of Ministers' Secretariat." Since economic practice had produced "many different forms" of consultation, it was left to the "statutory stipulations" for the combines to determine the "composition and tasks" of such bodies.[24]

3. More Efficient Use of Capital in the Combine

Neither the changes in the organizational management buildup nor the legal codification of tasks, rights and obligations on the part of the combine management and the combine enterprises are being done for their own sake. Rather, their purpose is to make it possible to better realize the catalog of goals that have been set. They are designed to create an institutional framework, so to speak, for the desired radical internal restructuring of the potentials that are united within the combine. This is the crucial issue. In other words, they want to increase potential capabilities by combining these potentials more effectively — a prodigious task within a combine.

For example, a flexible installations park is a prerequisite for the manufacture of new products that meet demand. However, in the single enterprise in the GDR, installations are almost totally inflexible for the short term and are only slightly convertible in the medium term — by way of investments. By contrast, substantial

changes and accompanying obvious productivity advances can be achieved within the combine by restructuring aggregates, reassigning production to different units and remodeling entire enterprises or parts of enterprises.[25] This is because regular rationalization has been neglected for decades in the GDR, old installations are still being used too long at high maintenance costs and, moreover, because there is a shortage of modern accessory equipment. The consequently so urgently necessary intensification advances can certainly be achieved easier and more rapidly in the larger enterprise system than in single enterprises, for the combine has at its disposal a far more comprehensive reservoir of different capacities, thus making possible a higher "degree of self-supply." In other words, with only limited allocations of new assets, the greatest importance is being placed on improvisation with existing installations.[26]

Considering these circumstances, one can also understand why the in-house construction of rationalization means by enterprises has been accorded a special role.[27] This role is that of constructing single pieces of equipment to solve problems in specific enterprises, developing procedures and promoting the use of interchangeable equipment. The in-house construction departments are designed to permit construction work to proceed while production is going on and in general to establish better links between construction work and outfitting processes.[28] Existing capacities for the in-house manufacture of rationalization means are merged in the combine and placed under the direct authority of the general director so that swift and effective rationalization programs may be assured. Quite often it is a matter of manufacturing single items which machine construction cannot be bothered with.[29] This means that it is much less a matter of highly efficient solutions than of somehow surmounting difficulties at all on short notice. Since, however, there has been mounting criticism of the high cost of this kind of in-house manufacture, efforts have recently been aimed at finding better criteria for evaluating these services (for instance, the benefits, the degree of acceleration for innovations, the release of manpower) and also at applying these criteria.[30] But this means that not every in-house construction program will meet with general approval from now on.

The intention is to use the stepped-up modernization of existing buildings instead of new ones to reduce both the expenditure of construction materials and construction's share of investments.[31] Investments are to be made more efficient and construction times substantially reduced by means of better planning and project-planning for new projects, development of a substantiated priority and sequence order for projects as well as changes in the productivity evaluation for capital goods.[32] It is anticipated in this regard that the general directors will come forth with a strong impetus for better investment decisions because of their broad overview of the branches and their proximity to production — this expectation is being held out even though state intervention in the investment process has increased.[33]

4. Intensification of 'Industrial Labor Resources'

Except for the "involvement of the general director,"[34] any progress in the "ensemble" of interlocking and mutually conditional intensification and production factors depends chiefly upon the efficient use of employees ("use of industrial labor resources") and their willingness to produce. With an employment figure of more than 90 percent of those of working age (including trainees) in the GDR, any

further expansion will also be severely restricted for the period of the 1981-1985 Five-Year Plan. The possibilities of a thoroughgoing rationalization in the personnel sector[35] are also a decisive criterion in the organizational changes, since without a centrally determined "self-production" by the labor force offices in the combine, new investments or those for expansion are frequently ruled out for lack of manpower. Numbering among the hoped-for "combine results" relating to the labor factor are the "release of manpower for other tasks and a saving of jobs,"[36] improvement in unsatisfactory work discipline[37] in a number of enterprises, a reduction in the apparently very sizable downtimes[38] including the accompanying unplanned costs,[39] efforts to provide skilled-worker trainees and a "curbing of fluctuation," which "has experienced a further negative" trend[40] compared to 1978. The release of employees and job-saving measures are therefore expressly a central concern of the combine decree (Art 21, par 1) and are considered by the "Joint Directive" to be a "central issue in assuring major production growth."[41]

Apart from the by no means new conflict of interest between plan targets and job reductions in the enterprise, the general restructuring situation that exists for the most part in the combine facilitates a simultaneous revision of the table of organization and the relinquishment of those positions "which are never actually to be occupied by workers"[42] but have thus far repeatedly been pushed by the enterprise manager as an optimum demand vis-a-vis his central office. Released workers are expected to result in particular from a greater centralization of combine functions (in administration as well as in production) and especially from certain auxiliary and secondary processes. To be sure, economic practice shows that just one of the substantial obstacles to a transfer of employees is the great physical distance that often exists between a combine's enterprises and parts of enterprises; added to this are housing problems.

The so-called Schwedt Initiative — "Few produce more"[44] is an official symbol for comprehensive rationalization in the personnel sector according to this formula: "Reduction in the number of existing jobs with a simultaneous increase in the level of quantitative and qualitative labor requirements."[43] As the result of expansion investments that are scheduled to double capital assets during the 1978-1981 period, the main enterprise of the Schwedt Petrochemical Combine, with 8,500 employees, is obliged to produce the 2,400 workers[45] needed for this (a good 25 percent of the workforce) from within its own plant by means of a "genuine reduction of slots"[46]; this is virtually tantamount to a cut in the wage fund imposed from above.

The great number of potential practical problems in transferring to a new workplace in the GDR will only be noted here. Even the hope of reducing fluctuation[47] in the GDR — the costs of which run into the billions according to GDR figures[48] — should not be raised too high considering such a radical, centralized regime of thrift. As it is, the GDR had decreed a general cost freeze for the managerial and administrative sector with its new guideline on financing dating from August 1979.[49]

Moreover, it remains to be mentioned that problems resulted for the Labor Code (AGB) because "the purview of Art 17, par 1, of the AGB" fully covered "only enterprises, but not the combine as a basic economic unit"[50] in its various forms. The AGB is used here expressly as an "analogy." In addition to the aforementioned by no means always positive aspects, the development of a more productive "regular workforce,"[51] the definitely visibly improved working conditions and a transfer and retraining of manpower within specific limits are only a few of the better manpower placement

possibilities that must be assessed positively from the standpoint of industrial management. But simply because of the size of a combine, many a factor that has heretofore placed obstacles in the way of increasing labor productivity — such as a system-related hoarding of manpower in the individual enterprises, for example — could be reduced to some extent, but by no means totally eliminated. An expansion of the opportunities for social service by the combine workforce (use of combine capacities for housing construction, vacation homes, daycare facilities and so forth) could provide an additional incentive for the workforce.

5. Conservation of Energy and Raw Materials

The GDR literature is fairly imploring the enterprises and combines to follow "paths to increased labor productivity that conserve capital and materials."[52] When one considers, for example, that more than 70 percent of industry's production costs go to pay the cost of materials, and more than half of all manpower in the producing sectors is used to produce and transport energy, raw materials and materials,[53] then one recognizes the importance being ascribed to the material-conservation intensification factor alone. To be sure, so far the leading role of the gross "industrial goods production" figure has had a negative effect when plan accounts are being balanced, because if there has been an increase instead of a decrease in the expenditure of materials, the enterprise or combine has even been "rewarded" in the form of "better plan fulfillment." Since March 1980, however, an important change has occurred: Now the performances of combines and enterprises are no longer measured solely by "goods production" but also by the new index figures for "net production" and "material costs per M 100 of goods production."[54] This is undoubtedly an important step in the right direction with regard to conserving energy and raw materials, whose increasing costs world-wide are placing great strains on the GDR economy.[55]

By way of an improved evaluation of productivity and a mobilization of scientific-technical progress, the economic leadership is expecting from the combines changes in production processes which save materials and make intensive use of raw materials. Says Guenter Mittag: "It is fundamentally important here to refine available raw materials to a higher degree and with the aid of modern technologies bring them to the highest possible stages of processing, thus further developing and improving the GDR's production structure."[56]

Future growth is to be achieved insofar as possible with constant levels of, or only slight increases in, energy and materials consumption, which is why the economic leadership also is not afraid to impose a quota system for energy, heating oil and vehicle fuels,[57] draw down stockpiles and order increased efforts to make multiple use of secondary raw materials.[58] Even private households are being penalized for substantially exceeding fixed heating norms through price increases for the excessive consumption of energy, gas and heat.[59]

The 1981-1985 Five-Year Plan calls for the construction industry[60] to employ designs that are economical in the use of materials in order to reduce specific materials consumption by 3.9 percent annually for rolled steel and lumber and by 2.5 percent annually for cement. Moreover, plans have been made to cut building costs by 15 percent by 1985; this is to be accomplished by switching from former construction methods to the practice of doing more remodeling of existing structures, thus saving materials. Better insulation of new buildings as well as the older,

renovated structures and technological improvements in the equipment that goes into buildings are supposed to cut energy consumption by 30 percent. It is hoped that the manufacturers of building materials will achieve at least three-quarters of their planned production growth without using additional energy.

These things cannot be done without substantial and active participation by the combines and enterprises. In addition to major changes in production processes, protracted technological innovations are also required. With the technical means and limited potential for innovation existing in the combines, neither can be achieved speedily or without great difficulty.

V. On the Conflict of Interest Between Combine and Combine Enterprise

1. Powers of the Combine Enterprise in Theory and Practice

At first glance, the status of the combine enterprise in the new combine decree appears to be not only unchanged but even strengthened from a formal standpoint. In contrast to the earlier phrase "responsible for itself," the combine enterprise is now described in Art 6, par 1, of the combine decree as an "economically and legally autonomous unit," although the narrow limits are made clear by this proviso in the text of the law: "within the framework of its integration in the reproduction and management process of the combine."[61] But considering both a debate over the status of combine enterprises — one that has at times been quite heated in recent years — and the guarded interpretation found especially in commercial law commentaries on the combine decree, one can see several unsolved problems regarding an issue that is so central to the new regulations.

The combine enterprise receives its assignments from the combine and is accountable to it.[62] It is tied into the industrial management cycle as determined by combine management and planning. In accordance with the principle of individual management, the enterprise director is responsible for accomplishing the tasks assigned. The scope of his relative autonomy is revealed by the very manner in which capital (working capital) is handled: The fact "that the portion of state property to be administered by the combine takes in the capital held by the combine enterprises as well as the combine's centralized capital"[63] is described as an "important advance in the legal representation of structured state property."[64] This means, however, that essential funds are centralized in the combine.[65] Enterprise financial transactions having to do with the state budget are also conducted through the combine. The question of liability is interesting in this regard. According to previously existing regulations, in contrast to the VVB the combine was also liable for the debts of its enterprises. But the new combine decree provides in Art 3, par 5, for a combine's liability for its debts as well as in Art 6, par 2,[66] expressly for a corresponding liability on the part of combine enterprises. The hitherto-existing ruling on a backup liability by the combine was dropped, it is said, because it had acquired "no practical relevance."[67]

The very extensive powers of a combine general director (the restructuring of production and the transference of funds within the combine, for instance) do not change the fact that the combine enterprise that operates according to the principle of economic accounting is basically subject to the principle of self-financing within the framework of its plan commitments. It has been remarked that the obvious discrepancy, only alluded to here, between formal autonomy as stated in the combine

decree and the actually existing limitations on enterprises within the combine system is not a contradiction; "rather, it presents an exact reflection of the present status of the socialization process."[68]

There are doubtless important reasons when the legal department of the GDR Council of Ministers expressly interprets the new regulations in such a way that the combine enterprise is indeed "integrated" but not "subordinated."[69] In the debate prior to publication of the combine decree, the emphasis in views on the status of combine enterprises had shifted from a "nonautonomous" position (frequently propounded by practicing economists from combines) to that of retaining a "relatively more independent" status, though with the following proviso: Since "the key areas...in effective management of the combine reproduction process are consistently to be handled centrally," changes in the "objective features and criteria" of "in-house responsibility" on the part of the combine enterprises should not conflict with these requirements.[70] Rather, in-house responsibility should acquire "new substance,"[71] for it is "no static entity"[72] since "main functions" of the enterprises pass to the combine.[73]

Horst Trauer, one of the GDR's experts on problems of organization, had already described this issue in 1973 as "one of the most complicated problems in the continued socialization of production."[74] One of the main points in the discussion at that time was whether the combine or the combine enterprises represented the lowest level and were thus the basic economic units in the GDR.[75] The USSR settled this question once and for all by converting to "associations" after 1973; there the "associations" — roughly comparable to combines — constitute the lowest level, not the enterprises.[76] A study conducted at the Bruno Leuschner Advanced School for Economics in 1978 was critical of the fact that "increased effectiveness will be hindered in the long run if, in contrast to the situation in the Soviet Union, the enterprise continues to be regarded and supported as the sole basic unit of social production."[77]

The scope of "in-house responsibility" by combines and enterprises and the principle of economic accounting as a method of socialist economic management are mutually exclusive.[78] The latter principle determines the scope and level of the industrial management mechanism. With regard to the forementioned debate, this is significant in that in the Soviet Union only the "associations" — thus the economic units that equate to the combine — operate according to economic accounting principles. The combine at present has basically a three-phase system for the economic accounting mechanism:

(1) Full application at the combine level;

(2) Application to the combine system's enterprises limited by overriding combine responsibilities;

(3) Application of "economic accounting within the enterprise"[79] to nonautonomous parts of enterprises and production units.

There were a number of reasons for retaining a relative autonomy and thus also the principle of economic accounting for the combine enterprises:

(1) The unwillingness of enterprises and workforce to give up existing rights certainly played an important role: "The new situation must first gradually be 'sounded out,' so to speak. Problems of interest are also involved, because the measures to be initiated may presumably or actually be in conflict with the distinct group interests of the combine enterprises."[80]

(2) Preservation of "autonomy" and the basic retention of the economic accounting principle lend themselves to the function of a control and buffer against the considerably expanded, real abundance of powers enjoyed by the general director of a combine. On the other hand, the principle of economic accounting serves to make the industrial management mechanism and productivity evaluation of the respective enterprises work better. To be sure, it is the GDR view that "an economically correct setting of prices"[81] is considered a precondition for the "effectiveness of the entire mechanism." Moreover, retention of the economic accounting principle makes it possible to avoid motivational weaknesses that are already apparent in the Soviet model, since here the units that are not legally autonomous are losing "the feeling of their responsibility for the success of production."[82]

(3) It is a prerequisite for the continued expansion of enterprises, thus of cooperation with "local organs," with particular reference to a frequently substantial physical distance between the combine enterprises.

Basically, the compromise solution contained in the combine decree can be seen in the definition of the combine in Art 1 as a "basic economic unit," which in turn points up the prominent position of the combine and a special importance in relation to its enterprises, one which tends to correspond to the Soviet interpretation of the association. Thus it is generally true in economic practice that the "combine management determines the degree of autonomy enjoyed by enterprises within the combine."[83]

The problems outlined here are sufficient to illustrate the divergence of interests between the combine and its enterprises and the obstacles to productivity stimuli that doubtless result.

2. Selected Intensification Tasks for Industrial Management in the Combine

Any analysis of even the most prominent tasks in setting up a "largely contained reproduction process" in the combine (according to the provisions of the new combine decree) would far exceed the boundaries of this study. This is already a fairly long-range process for the majority of combines. Trends and the problematics involved in reshaping industrial management capacities in the combine, as well as the question of possible prospects for success, cannot be elucidated systematically here; only selected examples can be offered — though supplemented by important changes in method that are becoming observable in the 1981-1985 Five-Year Plan as regards the industrial management sector.

The economic leadership is anticipating advantages for the combine from a generally high degree of centralization of industrial functions. Although this may lead to benefits for combine enterprises individually, as a rule it will not. This is because major changes in or the virtual destruction of the hitherto-existing industrial structure of combine enterprises will cause disadvantages to predominate, at least in the short run for a period of conversion and adjustment. A total

relocation of industrial manufacturing programs that enhance the plan and the profit situation can also lead to a longer-term disadvantage, which can scarcely be offset by potential financial compensation from the combine leadership.

The emphasis in GDR economic life is on economic productivity aspects of the centralization and specialization of industrial management functions in the combine, as well as the "standardization of important processes";[84] in addition to economic motives, hidden power interests on the part of top combine officials cannot be ruled out here.

One of the main objectives is the establishment of centralized R & D facilities for the planning and development of products — including the expansion of design centers[85] — for specific product lines from the "idea through to the successful product,"[86] particularly for export. Behind this is the endeavor to gain a better grasp of the entire process than before, from "demand and market research" through "technological realization"[87] all the way to sales; this is because in the past, for reasons of plan fulfillment, the "for the most part poorly developed market research" in the enterprises and combines had "often been dropped or reorganized" as an in-house activity.[88] Among such "combine results" of industrial management are: the dismantling of "engineering offices" and their reorganization into "Technological Rationalization Centers" (TZR) as relatively self-sufficient combine facilities;[89] the concentration[90] of an "often inadequately" organized "materials procurement, storage and supply operation";[91] a forced development of the previously unsatisfactory expansion of centralized manufacturing operations;[92] or a specialization of the "product structure according to effectiveness criteria."[93] To be mentioned equally in this context are the concentration and resulting improvement in the mechanization of auxiliary processes — through the creation of special maintenance enterprises,[94] for example — or rationalization by centralizing administrative affairs. In the latter case in particular, there is considerable reason to doubt that any advantages will be forthcoming.

Basically, two essential aspects play a role here: One concerns the increased productivity from concentration and rationalization stimuli as a result of reduced costs; the other concerns the elimination through the restructuring process of causes and obstacles to industrial management functions that have hitherto been exercised only to an inadequate degree. Quite apart from existing pricing and valuation problems,[95] this is particularly true of the sector for accounting and productivity evaluation. In addition to other new plan index figures[96] (net production, for example), introduction of the "end product" index figure that dates from 1 January 1979, and is considered a beneficial "statement of result for the combines,"[97] is also playing an important part in the economic debate. In particular, the special index figure for "yield on the end product" is designed to establish a better incentive and productivity criterion in economic units.[98] Warnings have already been issued, however, against "excessive expectations"[99] with regard to the validity of the "end product" index figure.[100] On the other hand, it is precisely the internal performance picture of a combine that is a very essential factor in more rapid advances in productivity.

Another weak spot is "independent planning" in the industrial sector. It is here that, despite appropriate regulations, there has been either inadequate or no organization in many enterprises of an in-house short- as well as longer-term "conceptual preparation of plans,"[101] no drafting of "development options,"

"intensification plans" or long-range production programs; there are a number of reasons for this ("too expensive, no time, no employees who are capable, information value too low"[102]). For the most part an "autonomous sector" for this function has been lacking in the enterprise.[103] Corresponding new provisions[104] in the 1981-1985 Five-Year Plan will doubtless be easier to enforce by way of centralized combine departments.

This study will forgo a discussion of the problems involved in the assignment of foreign trade enterprises to the combines in accordance with the combine decree; regardless of complex provisions,[105] a closer operational interdependence that is developing with the combine can only be advantageous.

Given a flexible practical application, the developmental directions of combine efforts at concentration that have only been touched upon here will certainly be able to unleash a certain productivity thrust for the short term if a number of existing weak spots are eliminated. Nevertheless, the conflict of interest that seems to be increasing rather than abating between combine headquarters and their enterprises is an obstacle that cannot be underestimated, especially since the economic leadership's most recent moves are even heightening the trend toward centralization, and thus toward a possible bureaucratization.

The first of these measures appears to be a new version of the principle of "structurally-determining planning."[106] This is an Ulbricht type of concept, a priority program of planning, incorporation and implementation of crucial economic innovation processes[107] by way of the new planning ordinance for 1981 through 1985. No matter how necessary this may be to the more rapid implementation of technical progress (in microelectronics, for example), the consequences that go along with it have already proven to be a negative factor once before — one of these consequences is an "improvement of the index figure system"[108] (probably through expansion). In the revision of the Contract Law that is still going on,[109] these peculiarities will play a role not only in the combine's external relations but also within the framework of the "internal enterprise cooperation" (production relations among the combine enterprises) that has been sharply expanded through combine reorganization.[110] This would indicate a general increase in the codification of commercial law covering the internal combine sphere.

Consequently, it is no mere coincidence that even in the GDR there are those who are warning against overestimating the effects of concentration,[111] and considering the "monopoly status"[112] now being accorded the combines, these warnings are definitely justified.

VI. Interim Balance Regarding the Combine Reorganization

The sought-after ideal of a combine as a totally "new economic organism"[113] is aimed chiefly at a new quality of industrial management in addition to improvements in the national economic situation. A conclusion drawn from a vast number of studies and essays in recent years is that the present reality of reorganization differs from this ideal by virtue of the mere fact of extremely different, even contradictory, statements regarding the best organizational structure for the combines. The move to another dimension, virtually a command for the majority of the enterprises, had led to obvious confusion by the fall of 1979 — for the lack of clear, detailed guidelines. Though the new combine decree does provide guidelines for a new type

of combine, judging at any rate by the existing system of strict centralized management and planning, these guidelines will have to be supplemented by more detailed regulations. It is possible that internal implementing regulations for specific branches — like those in the pricing sector — could play a greater role than before in achieving a more flexible adjustment of the organizational structure to everyday economic conditions. Consequently, a swift and smooth solution for the complex relationships that have to be reordered can hardly be expected for the short term.

A balance sheet of positive and negative structural effects for the economy and for industrial management would therefore be premature. An essential prerequisite is the patience to get through a lengthy adjustment period, for sufficient patience to allow reform processes to mature has never been one of the GDR's strengths. With this one reservation, a number of positive effects appear basically possible; they could be the result of activities generated by an improved — but just as risky — style of industrial leadership. This applies, however, only insofar as all other conditions satisfy the requirement of a new quality of "internal containment" in industrial operations and actually allow enough leeway for the activities demanded of combine managers with respect to the "how" of production. This latter condition concerns powers at the ministerial level in particular. If those very principles of control described by the SED Central Committee's Central Institute for Socialist Economic Management should be fully implemented as far down as the combine enterprises, the unquestionably meaningful beginning of a release from encrusted structures could be blocked. Quite apart from this, important conflicts of interest still remain unresolved or are merely being shifted from one point to another; other problems of detail also constitute risk factors that can scarcely be comprehended at this time. Added to this is the fact that in a phase of extreme economic strain and mastery of pressing economic problems, it would probably be virtually impossible to complete an organizational reform of this magnitude without major initial difficulties and frictional problems. And last but not least, an especially aggravating factor continues to be the GDR economic system's already more than latent tendency toward bureaucratization and unwieldiness. Large Western corporations "have been endeavoring for years to reorganize their giant apparatuses — which could not be made more transparent despite outsized staff departments — into comprehensible units that are more or less partially autonomous."[114] By contrast, GDR enterprises frequently suffer from an insufficient internal clarity even in units that are comprehensible. Though the information systems may have been improved, they nonetheless provide only inadequate aids to the preparation of decisions, largely because of very considerable price distortions and unresolved pricing problems.[115] It is for this very reason that the combine management is clearly limited (in its efforts to arrive at more efficient forms of large-scale enterprises).

In addition, the radical internal redirection being sought for the potential that is bound up in the combine requires general directors who — despite meager material incentives for themselves — will develop a variety of initiatives in the face or all bureaucratic obstacles, but who will nevertheless pursue the state's objectives. They must be able to use innovations — radical but inexpensive ones — to extract substantially greater results mainly from existing capacities without any large new investments, with the lowest possible manpower potential and with only minimal increases in the use of energy and raw materials. Thus, the most serious

problem for combine reform would seem to be that of finding sufficient numbers of this kind of ingenious "supermanager" who will toe the party line at the same time.

55. To be sure, in the balancing of accounts problems still arise for the enterprises and combines to the extent that they have to show "net production" for the very first working day of the following month. At that point they know neither the figures for "materials consumption" nor the "inventory changes in uncompleted products," so they use as aids the coefficients relating to "industrial goods production." Even if the resulting errors are corrected a month later, it is virtually impossible to arrive at an error-free accounting for the entire combine. Cf G. Frischmann, H. Schubert, "Experiences and Problems with the New Index Figures," DIE WIRTSCHAFT, Vol 6, 1980, p 17.

73. In regard to the overall issue, see also the remarks of N.V. Klimin (Leningrad): "Relative Economic Autonomy and Peculiarities in the Functioning of the Socialist Enterprise," WISSENSCHAFTLICHE ZEITSCHRIFT DER TECHNISCHEN UNIVERSITAET DRESDEN, Vol 3, 1976, pp 373-377.

74. Cf Horst Trauer, "On the Organization of Relations...," loc cit, (footnote 71), p 364.

75. Cf, for example, H. Feurich, "On Improving Planning and Productivity Evaluation," WIRTSCHAFTSWISSENSCHAFT, Vol 5, 1978, p 602. E. Manz, "Problems of Organizing Economic Accounting in the Combine," WISSENSCHAFTLICHE ZEITSCHRIFT, Karl Marx University, Leipzig, Vol 2, 1978, p 254.

76. Cf Horst Steeger (review of a Soviet publication), "Improving the Economic Mechanism in Developed Socialism..., Moscow, 1975 (in Russian)," WIRTSCHAFTSWISSENSCHAFT, Vol 6, 1976, p 909.

77. Walter Burian, "Thoughts on the Status and Further Development of Branch Management in the GDR System of Socialist Industrial Management," WISSENSCHAFTLICHE ZEITSCHRIFT, Bruno Leuschner Advanced School for Economics, Vol 3, 1978, p 103.

78. The principle of economic accounting, once known by the more comprehensible name of "principle of in-house profitability," is considered both as an "economic category of the socialist mode of production" and as a "method for the systematic economic administration of enterprises," or "method of socialist economic administration" with the aid of commodity/cash relationships and valuation categories (prime costs, profit, price, interest and so forth) according to the principles of profitability (drawing a balance). Cf Authors Collective, "Socialist Industrial Management," textbook, third edition, (East) Berlin, 1975, p 198 ff; and Authors' Collective, "Socialist Industrial Management for Engineers," (East) Berlin, 1978, p 1978.

79. Economic accounting within the enterprise is considered basically a limited method of socialist economic administration in nonautonomous parts of

enterprises, a method that is not based on commodity/cash relationships (no proceeds from the sale of goods). Also see Authors' Collective, "Socialist Industrial Management for Economists," technical school textbook, (East) Berlin, 1976, pp 145, 146.

Tasks of Industrial Psychology

East Berlin TRIBUENE in German 29 Aug 80 p 5

[Interview by Jutta Wolf and Manfred Strzeletz with Dr Baerbel Matern, lecturer, Technical University, Dresden: "Training--Not for World Records But for New Work Tasks; GDR's Industrial Development Poses New Tasks for Industrial Psychologists"]

[Text] Dr Baerbel Matern was born in 1943. After graduating from high school, she studied psychology at Dresden Technical University from 1962 to 1967. Subsequently, she engaged in graduate studies and then worked as a research assistant at that university; in 1971, she took the Ph.D. degree. From 1971 to 1973, she worked for the industrial health service and in 1973 returned to the Technical University. Dr Matern lectured in the fields of industrial and general psychology. In 1975, she was appointed Assistant Professor and in 1977, she took the degree of Doctor of Science. Dr Matern's work at Dresden Technical University focuses on psychological work analysis and psychological training procedures for the industrial sector. Dr Matern is a member of the Council for Psychology at the GDR Ministry for University and Technical School Affairs.

What are the objectives of industrial psychology? What results has it produced so far? What problems is it confronted with? These and other questions were asked by many of the 4,000 researchers from over 50 countries, who a few weeks ago participated in the 22nd International Psychology Congress in Leipzig. Aside from psychologists, there were above all physicians, biologists, educators, philosophers, operations and process analysts. Dr Baerbel Matern participated in this international exchange of opinion and TRIBUENE talked to her about the tasks and possibilities of this scientific discipline.

[Question] What are the tasks of industrial psychology?

[Answer] Industrial psychology analyzes and evaluates work processes so as to modify them and to prepare the workers--by means of training and qualification measures--for new tasks. Furthermore, it examines the interrelationships between

certain types of work and their long- and short-term effects on the worker. The objective of the psychological modification of work is the unity of high productivity, freedom from negative influences, and personality development through work. This means: Aside from a high level of performance, the working processes must be designed so as not to be detrimental to the workers' health. That is to say--in accordance with the World Health Organization's (WHO) definition of health--not only freedom from disease, but also emotional and social well-being. Work is to contribute to the development of the personality.

[Question] What are the methods of your discipline?

[Answer] In analyzing work processes, industrial psychology draws on a large number of methods. Evaluation standards and criteria help in the assessment of the results of the analysis. We also examine the short-term effects on man of certain types of work, i.e. the effects produced during one particular work shift. Above all, I am referring here to fatigue, monotony, saturation, stress, etc. Long-term data, i.e. changes that occur in the course of several years of work and that affect man, his skills and his attributes are analyzed as well. Aside from being a practical discipline, industrial psychology has been developing in our country into an independent theoretical discipline. This theoretical advance is essential for effective work in industry, for "nothing is more practical than good theory."

[Question] How do you apply to practical work the results obtained?

[Answer] Frequently, the measures recommended by the psychologist are of an organizational nature. They may concern the division of labor among various individuals or the individual organization of working processes, including breaks. Here one should also include training measures aimed at improving performance.

[Question] Are there points of contact with other disciplines?

[Answer] With a great many disciplines. Depending on the branch of industry, the industrial psychologist collaborates with technologists of diverse disciplines; he or she cooperates with all work analysis-related disciplines, above all industrial medicine and industrial hygiene.

[Question] Can the scientists working in this field accomplish all these tasks?

[Answer] The GDR's research potential in the field of industrial psychology is not very great. Thus international and interdisciplinary cooperation and careful selection of the research projects are absolutely essential. Moreover, as a result of the development of technologies and procedures, industrial psychology is continuously confronted with new problems. To solve all these problems through their own research efforts exceeds the possibilities of the GDR scientists. To some extent, our research projects are coordinated with the projects pursued in the other CEMA states. Through division of labor, the socialist countries collaborate on solving various problems. Interdisciplinary cooperation is essential for solving key industrial problems and for ensuring the transfer of research results to the production process.

[Question] In our republic, what are the points of main emphasis?

[Answer] Our research focuses on the development of psychological work analysis and evaluation procedures for various branches of industry. These procedures are prerequisite to broader participation in the planning and correction of working processes.

[Question] Specifically what is this scientific discipline concerned with in regard to the modification of working processes and equipment?

[Answer] Changes in regard to equipment can be effected in various ways, e.g. through modifications concerning the division of functions between man and machinery. Modifications in the field of regulating and control technology--i.e. the point of contact with man--are a special case in this respect. As regards the modification of working processes, we are concerned with the division of labor among the workers. The presently much-discussed trend toward transition from assembly line work to modular production is an example of work modification that involves changes in the division of labor among the individuals concerned. The objective is to bring about a combination of working processes and a division of labor that neither bore nor overtax the individual.

[Question] How is it that more and more enterprises are abandoning assembly line work, changing over to modular production?

[Answer] Assembly line work is the prototype of psychologically badly organized work: It is monotonous and degrading. Modular production offers greater work satisfaction. The worker can choose working processes himself. The work is more varied and gives the worker the opportunity to use and--to some extent--develop his or her skills. Monotony no longer exists.

[Question] As a result of the development of technologies and procedures, the demands made on man are changing more and more rapidly. How can we reduce the periods of vocational adjustment and make the working processes more efficient?

[Answer] Now as ever, a vital task of industrial psychology is the development of training and adjustment procedures and of job-related training and advanced training. Psychological training procedures consist in the transmission of the requisite knowledge and skills, which must be practiced systematically and repeatedly. In this work, the psychologists use theoretical concepts of the psychology of reasoning, memorizing and learning. In this regard, the congress presented a great many new findings. Good examples of psychological training procedures are training programs that extend over several weeks and that combine theoretical knowledge with practical exercises in the production process, training programs for simulation facilities, e.g. power plant trainers, and adjustment aids in the form of external stores to be used individually.

[Question] Provided it is possible to make such generalizations--what are the principal training objectives?

[Answer] In view of the rapid development of technology and of the increasingly complex working processes, the main objective is to train the ability independently to develop professional knowledge and skills. On account of the fact that the workers' general education has been improved, this objective is now more readily attainable. We want to develop training procedures that--rather than making the

workers consumers of well-arranged knowledge and didactically well-taught skills--make them the psychologist's active partners in the development of new knowledge and skills.

[Question] So the industrial psychologists contribute to personality development?

[Answer] The development of the personality is the objective of psychological work modification. Work is the most important sphere of human life. Man spends most of his waking hours working. A good work collective is a vital factor in the development of personality attributes. The extent to which work-related cooperation and communication are practicable and the way in which performance evaluation and feedback is carried out are important criteria in regard to the evaluation of the quality of work modification measures.

[Question] How can industrial psychology help to make work easier, more interesting, more varied and more pleasant?

[Answer] To some extent, basic research in industrial psychology is concerned with examining the effects on man of various types of work. To this end, it is necessary to determine the degree of complexity, at which a job is experienced as interesting and stimulating, as neither overtaxing nor boring, and at which the work thus serves further to develop skills and attitudes. Such interrelationships are not generally constant; rather, they are dependent on personal constellations. The worker's qualifications and age are of great importance. On the basis of such research results, we are able to make recommendations regarding psychologically well-organized work and to make predictions concerning the effects of such work, e.g. absenteeism due to illness, turnover, and job satisfaction.

[Question] So appropriate work process modifications serve to reduce absenteeism due to illness?

[Answer] Undoubtedly, absenteeism due to illness and the quality of the work process modifications are closely interrelated. Badly organized, dull types of work that require only a fraction of the skills acquired not only generate monotony, but also give rise to job dissatisfaction and diminish work motivation. A negative view of one's work tends to prolong illnesses and also leads to more frequent visits to the doctor. It has been proved that the incidence and duration of illness depend not only on the state of health, but to a large extent on the way the individual views his or her work situation. The difference in absenteeism due to illness between individuals doing interesting and responsible work and individuals doing dull, monotonous work amounts to several percentage points.

[Question] As the facilities grow larger and more modern, a higher level of technological discipline is required; without such discipline, there occur breakdowns causing great damage. Can you help to prevent this?

[Answer] I think we can. Through analyses, we have shown again and again--and the congress, too, adduced telling examples to this effect--that in highly automated industrial enterprises a large percentage of the breakdowns is attributable to operating errors and that these errors account for most of the repair costs. One of the problems concerning highly automated equipment is the low degree of human involvement. Under normal conditions, man only performs control functions.

Thus the worker has fewer opportunities in the normal working process to use and further develop his or her knowledge and skills. By various methods, industrial psychology is trying to solve this problem. Firstly, we have been able--through accident-prevention training--to compensate the infrequency of learning possibilities in the normal working process. Secondly, we are testing various ways of letting the worker take over functions that in the past were assigned to other occupational categories, in order to give the worker more opportunities for independent, active work. For example, in addition to their normal duties, equipment operators have been entrusted with laboratory analyses and simple maintenance work.

[Question] What becomes of those who are tripped up by scientific-technological progress?

[Answer] In our society, technological progress does not trip up anybody. If as a result of the introduction of new production systems or rationalization measures fewer workers are required, the workers in our country are in time prepared for new work tasks, which are in accord with their level of qualification or for which they acquire the skills necessary. The effects of unemployment on the development of the personality, which were intensively discussed by representatives of Western countries at the 22nd International Congress for Psychology, are only of theoretical interest to us.

[Question] Did your academic discipline gain any new insights at the congress?

[Answer] The congress provided many new stimuli. An important experience was the international integration of theories and concepts that in the past were studied totally independent of each other. Likewise, the integration of problems pertaining to industrial psychology with problems concerning personality development was of great significance. Of great interest were the symposia on sociotechnological systems, on mental strain on the job, on stress at the work place and on certain aspects of activity regulation. Our work was given fresh impetus by the fact that particular subjects were discussed by researchers from various branches of psychology. However, in view of the large number of new theories, methods and results presented at the congress, a comprehensive evaluation will take several months.

Importance of Work Safety

East Berlin TRIBUENE in German 22 Aug 80 p 7

[Interview by Inge Ruthe and Lilo Porada with Prof Dr Horst Rehtanz, engineer, director, Central Work Safety Institute, Dresden: "Safe Work Maintains Satisfaction and Improves Performance Quality; Work Safety Is Not Achieved Apart From or in Addition to, But Always Together With Production"]

[Text] Prof Dr Horst Rehtanz was born in 1927 in Petriroda, Thuringia. Upon completion of his studies at Karl Marx University, Leipzig, he took his doctorate at Freiberg Mining College. From 1950 to 1954, Prof Rehtanz was a member of the State Planning Commission. From 1955 to 1970, he successively held the post of technical director at the Karl-Marx-Stadt Pipe and Cold Rolling Mill, at the

Freital "8 May 1945" Steel Mill and at the Burg "Hermann Matern" Rolling Mill. Since 1971, Prof Dr Rehtanz has been holding the office of director of the Dresden Central Institute for Work Safety at the State Secretariat for Labor and Wages. In 1971, Dr Rehtanz was elected deputy of the People's Chamber. He is a member of the FDGB [Free German Trade Union Federation] fraction and a member of the Committee for Labor and Social Policy.

[Question] We have been fortunate in that since the beginning of the year there have been fewer industrial accidents than during the corresponding period of the preceding year. What are the reasons underlying this positive development?

[Answer] In the first 6 months of 1980, industrial accidents declined by 7.01 percent, as compared to the first 6 months of 1979. The accident rate, i.e. the number of industrial accidents per 1,000 workers, dropped from 15.41 to 14.32.

[Question] In this regard, what was the situation 20 years ago?

[Answer] In 1959, the accident rate still was as high as 48.87. By 1979, it had dropped to 30.1. As compared to 1959, the number of industrial accidents decreased by 38.4 percent. During the same period, the incidence of fatal accidents declined by 56.2 percent.

[Question] Is this a consequence of the unity of economic and social policy?

[Answer] Undoubtedly. A high level of occupational safety is a basic concern of our socialist society. The unity of economic and social policy has also led to a more effective utilization of the objective and subjective conditions concerning the implementation of the party and trade union resolutions and of the legal norms and plan targets in the field of occupational hygiene and safety.

[Question] What is this reflected in?

[Answer] To give only one example of many: According to the report of the Central State Administration for Statistics concerning the implementation of the 1980 economic plan in the first 6 months of the year, 110,000 jobs were modified or restructured by means of the application of scientific-technological results and of scientific work organization measures, and difficult and unwholesome working conditions affecting 20,000 workers were eliminated.

[Question] In our country, what is the role of work safety?

[Answer] The role of work safety is determined by the position of man in socialism. Man is the central element; everything is done for the benefit of the workers. This is reflected in the principle of the unity of production and occupational safety. This means that all of the measures aimed at increasing production and labor productivity must at the same time meet the requirements of occupational hygiene and

safety. Conversely, the work safety measures must not impede production. Since under socialism the management and planning work procedes from the needs of the people--which, as is well known, include the need for health, enjoyment of life, and job satisfaction--the work safety requirements cannot be met against, apart from or in addition to production; they can be met only through the integral unity linking occupational safety with the reproduction process.

[Question] Does work safety improve performance?

[Answer] Certainly, for injuries to health lead to a reduction in the social work potential and to personal suffering; they impede personality development and are a great drain on the social funds. Frequently, accidents also involve loss of materials, equipment and facilities. We have learned from experience that safe work places and equipment--i.e. implementation of the quality principle of maximum safety--affect work and production safety and product quality and promote production continuity. Working conditions characterized by a high degree of work safety, including observance of the threshold values concerning occupational hygiene, are prerequisite for enabling the workers fully to concentrate on the task at hand and for promoting their personality development.

[Question] In this regard, what are the conditions in the capitalist countries?

[Answer] Occupational safety is subordinated to the employers' only objective, namely profit maximization. This goes for the work safety measures not taken and for measures intended to protect the employees such as are adopted on the basis of legal norms and state or company programs. Undoubtedly, this approach yields a few results that scientifically and technologically are on a relatively high level and that benefit certain groups of workers.

[Question] But surely there are legal regulations.

[Answer] Naturally. And in addition, there are control organs, associations, specialists in enterprises and scientific institutions, professorships at the universities. However, it is obvious--and the high accident rate is proof of this--that work safety measures are adopted only insofar as the workers in a bitter class struggle wrest them from the employers and insofar as the employers permit them so as to improve the capital utilization conditions. Certain advances have been necessitated by the competition in the national and international markets. Moreover, occupational safety (production of work safety equipment, physical protection devices, and propaganda) has turned into a field for profitable capital investment.

[Question] And in the FRG?

[Answer] The FRG is no exception. According to the 1980 Accident Prevention Report of the Ministry for Labor and Social Affairs--which incidentally presents the results obtained in 1978--the industrial accident and occupational disease rate amounts to 83.4. In the FRG, the Bonn Friedrich Ebert Foundation published a paper on "Occupational Safety and Labor Protection in the Two German States." Allow me to quote from this paper: "Regarding the implementation of occupational hygiene and safety measures, the GDR has likewise been very successful. Per 1,000 full-time workers, the results achieved in the GDR in regard to work safety exceed those of the FRG. In this regard, however, one must take into consideration that in the

GDR intensive accident prevention--for which in the FRG the legal foundations were laid not until the second half of the 1960's--was initiated as early as the beginning of the 1950's. In this field, the GDR is in the lead and this gap must be closed--in the interest of the employees."

[Question] How do the GDR trade unions exercise their right of work safety control?

[Answer] Without the active participation of the trade union functionaries and without the control exercised by the work safety inspectors and the numerous volunteer functionaries in the enterprises, we would not have reached our high level of work safety. The work safety program is an integral part of the FDGB's constitutional right of "comprehensive codetermination in the state, the economy and society." The Labor Code and the Work Safety Regulations define the pertinent rights. Codetermination begins with the establishment of legal norms; it is laid down in the plans and firmly established in everyday life.

[Question] What are the primary concerns of your institute?

[Answer] Our research focuses on the following fields:
--Further development of effective work safety by integrating it in management and planning and in the incentive programs;
--increasing the effectiveness of education and training in the field of work safety;
--improving the workers' technological and organizational protection against accidents;
--improving the workers' protection against noise and vibration;
--increasing the effectiveness of the protection against noxious substances;
--ensuring work safety by means of protective devices to be used by the individual worker.

[Question] What is the significance of practical work in this respect?

[Answer] The scientific research work is carried out in close collaboration with the people engaged in practical work. The transmission of the research results takes place at an early stage, namely during the joint problem-solving efforts; it is carried out through patents and standards, through incorporation in the legal norms and through our own recommendations. There are other contributing elements, e.g. our information days, the publications on the various forms of training and advanced training, our journal ARBEITSSCHUTZ UND ARBEITSHYGIENE [Occupational Safety and Hygiene] and the Occupational Safety and Hygiene Exhibition.

[Question] Who are the most important partners?

[Answer] On the one hand, we obtain important information available in the GDR and abroad from scientific literature, patent specifications, documentations, conferences and congresses. This year (1980), our institute has become the National Center of the International Information Center for Occupational Safety and Hygiene of the International Labor Organization (ILO). For our work and for all interested parties in the GDR, we thus have at our disposal a large store of international knowledge and experience. Through many years of cooperation, we are linked with the work safety institutes of the socialist countries.

[Question] And on the other hand?

[Answer] In the realms of science and practical work, work safety as an interdisciplinary field can be become effective only through the cooperation of the most diverse fields such as technology, medicine, the natural and the social sciences, pedagogics, psychology. In 1979, we established the Research Association for Work Safety, in order to make work safety research more effective.

[Question] You are a scientist and at the same time deputy of the People's Chamber. What interaction is there between these two functions?

[Answer] In my capacity as deputy of the FDGB fraction, I am a member of the Committee for Labor and Social Policy. Through this function, I obtain a great deal of information for my work as director of the institute; moreover, as a deputy I am provided with many opportunities effectively to apply to practical work the results obtained by the staff members of the Central Work Safety Institute. In the Committee, we are dealing with problems concerning utilization of the social work potential. In this regard, the deputies are concerned above all with reducing absenteeism due to illness, with problems concerning work safety and with modification of the working and living conditions.

[Question] At present, what are the limits of the work safety program?

[Answer] Since in our country there are no limits based on the social system, the only obstacles are found in areas, where we have not yet been able to identify all the causes underlying injuries to health at the work place. Insofar as we can throw light on the various causes--this goes for potential as well as for present hazards--we will be extending the foundation for pertinent measures and means.

[Question] Do you think we may be able to eliminate industrial accidents caused by human error by entirely relying on technological means?

[Answer] In accordance with the order of priority of the work safety measures and with Article 3 of the Work Safety Decree, we are always interested in application of technological means. Naturally, human error cannot entirely be ruled out. But it is imperative that we modify the working conditions so that errors are largely eliminated. The physical and psychological conditions governing performance are of crucial importance.

[Question] Could you name some of these conditions?

[Answer] We must develop and consolidate work safety-related attitudes, needs, interests, feelings, skills, knowledge and habits. And here is another practical insight for all those who bear responsibility in the field of occupational safety and hygiene: If accidents are caused by faulty conduct, the countermeasures should not be based on a simple reversal of conduct. It is necessary to find ways of preventing faulty conduct through technical or organizational measures.

HARD REALITIES OF ECONOMIC SITUATION DESCRIBED

Warsaw ZYCIE GOSPODARCZE in Polish No 43, 26 Oct 80 p 3

[Article by Stanislaw Chelstowski: "The Current Economic Situation--Harsh Realities"]

[Text] Debate about the sources of current crisis and about the process of renewal naturally involves, first and foremost, the social and political sphere, tending to find it in the causes of distortions while perceiving the foundation for a way out of the difficulties in the enhancement--at times, indeed, restoration--of socialist democracy. In a long-term view, this is certainly a fundamental issue. Yet, while working out changes in this sphere, we should not forget about the current economic situation which is decisive for matters that, though perhaps more pedestrian, profoundly affect society's mood, in other words, the possibilities of maintaining the standard of living of basic segments of the population.

Such possibilities are slim, and, to stay close to hard economic realities, it should be said they are minimal. In the coming weeks or months we are, in fact, about to confront further imbalances in the essential economic disproportions with all the consequences this involves. Also, no realistic opportunities can be seen for obtaining some external resources to mitigate this dramatic situation.

After Three Quarters of the Year

While raising the problems of the current economic situation, I am aware that this is not an issue society sees as the most "important" at this time. It is not the most important because taking account of economic realities in many cases undermines lofty attempts to accomplish change in other areas. Another reason is that discussion of economic possibilities, or rather impossibilities, is frequently regarded as an attempt to torpedo social activism and to argue that political renewal should be put off until better times, while coping, for now, with the daily routine work. I have no such intentions--on the contrary, as I will point out later--I believe that profound and rapid change is needed precisely in the economy because this is the field in which renewal should be accomplished with particular intensity. This is just the reason, however, why one needs to know the situation as it really is and to realize that, unless the belt is tightened hard, we will be unable to emerge from the current economic crisis, which will be projected with exceptional force onto the entire process of modifications.

Three trends seem to be most important in the present situation. They involve industrial materials supply, foreign trade and agriculture. As a consequence, they are bound to have an unfortunately adverse impact on the domestic market.

Industrial output (counted as value of sales) rose 3.6 percent over the first 9 months of this year. This increase could be regarded as fair, if not for the fact that it is due to the results of the first 2 quarters. According to official data, in August industrial production was 10 percent below last year's figure, and it was 3 percent lower in September. It is difficult to assess to what extent this represents an actual production decline and to what extent it is due to the fact that enterprise managers began to submit unaltered information. Moreover, the fourth quarter cannot be expected to bring marked improvement in output because this is not warranted by supply possibilities, as estimated at this time.

The August-September decline in output is most frequently blamed on strikes in many work establishments. They can be seen as its most immediate cause, the last drop that completed a long-existing economic disintegration.

Its cause should, therefore, be analyzed more in depth, if we are to find a long-term solution now. The critical situation in industrial materials supply has been developing for a long time and it began to be felt with particular acuteness 2 years ago because of stoppages and power outages. Its causes were to be found in erroneous economic policies, a virtual atrophy of central planning and deterioration of overall economic effectiveness. There is no room here to anlyzee them, but it is beyond doubt that these causes were for the most part rooted in internal, mostly subjective, conditionings, to use a term recently in fashion.

Unsound subjective decisions changed, however, into objectively existing realities. These realities would have been exposed sooner and much more boldly were it not for the steadily increasing foreign debt. Opportunities to incur more debt are, however, not limitless. At this time, if we have not reached it yet, we are very close to the threshold where it will be impossible to increase Poland's debt, or, in any event, it will be impossible to increase it in a manner which could allay our domestic difficulties. I will return to this problem later.

The strikes were, among other things, an outcome of escalation of this state of affairs. This form of protest of the working class obviously enhances existing difficulties, but it was recognized by many workers as necessary for removal of the underlying causes rooted, to put it comprehensively, in the methods of exercise of power, including the modes of economic management and control. It is in this sphere, therefore, that we must work out radical change. Not only because this is the only way to remove original underlying causes of current difficulties, but also in order to prevent further work stoppages which--regardless of the intentions--additionally unsettle the economy.

Before I return to my discussion of the current economic situation, I will add one more comment. Wages undoubtedly rank high among the workers' demands. From the social point of view, they have a valid justification in the increase of living costs over the recent years. At least two conclusions must be drawn from this. First, current pay raises should not be regarded as wage increments through

which various disproportions and income irregularities that have developed over the years whill be equalized. Instead, they should be viewed as compensation for the rising prices of basic foodstuffs with this compensation going, in the first place, to those most affected by price increases. Second, hopes of regaining equilibrium should not be related to inflationary methods, because the public does not want to accept them--at any rate, not in their present form.

This observation influences my assessment of the economic situation in which a declining trend in output is accompanied by unusually rapid increases in personal incomes. The latter can no longer be equalized by price increases unless they are equalized very slightly and only in higher income brackets.

How Can We Reverse the Trend?

Thus, the fundamental question is now reduced to an explanation of the causes of the downward trend in industrial output in recent months, which at the same time will clarify another problem--can this trend be reversed once the subjective causes are removed?

As mentioned earlier, the materials supply situation is the fundamental cause. A very major portion of industrial raw materials supply is imported (a more precise determination of what percentage of total supplies this portion constitutes is, in my opinion, impossible, while reliance on existing prices may lead to mistaken conclusions). This portion is even more significant--with the current distribution of co-production--because of supply shortages rapidly impacting on virtually all of industry. Meanwhile, import possibilities are extremely limited for the next several months. Suffice it to say that credit repayment and servicing during the current quarter and the subsequent one substantially exceed estimated export revenue.

Considering that the bulk of obtainable credits must be allotted to increased imports of grains and other farm produce, few resources are left for industrial supply, fewer than in a comparable period in the past years. On the other hand, reserve supplies of many important raw materials and production materials are low (primarily in metallurgy, chemical industry and light industry). Furthermore, there is the situation in the power industry where planned repairs have not been completed in electric power plants (88 percent of the plan for the first 9 months of the year), while by September 1 none of the turbine units planned for completion this year had been put into operation. Coal reserve supplies in power plants in early September were nearly 0.7 million tons less than a year before.

We are no better off with domestic raw materials, especially coal. We fully understand that the miners' demands are well-founded--but this does not alter the fact that at least in the immediate future, if these demands are met, a definite decline in extraction output must follow. It will not be possible to make up for this decline by improved organization of work. A similar situation obtains in copper and in some other raw materials. Export restrictions cannot--or at least should not--be considered, because they are bound to affect import possibilities.

Thus, the current supply situation carries the threat of a chain reaction leading to stoppages in a very substantial segment of our industry. It would be an uncontrolled reaction with all the consequences this entails. It appears, therefore, that the only solution lies in deliberate centralized channelling of all available materials supply to selected subbranches, coupled with equally deliberate and centrally controlled restrictions on, or even periodical halting of, production of particular commodity groups.

Decisions on such matters must obviously be preceded by appropriate calculations which should include not the benefits, but minor losses, primarily those perceived from society's point of view. Such calculations should be made on the central level since only on this level is there a chance for this point of view to be considered at this time. This statement can be supported by the fact that there is one industrial sector--the capital goods industry--that exceeded its plan for the three quarters substantially, by 25 billion zlotys, irrespective of difficulties in materials supply and strikes. This means that a comparable sum must be added to increase investment outlays, although with the reduction of the actual scope of investment, these capital goods will for the most part end up in storage sites and warehouses, thus increasing the value of uninstalled machinery and equipment. (And that value is already sizable--as of 31 March 1980 it was 48.5 billion zlotys.) On the other hand, deliveries of export-designated goods fall behind the plan, principally with reference to the second payments area (capitalist countries). The annual plan of exports to the second payments area was 67.6 percent fulfilled over the 9 months of this year.

Centralization is needed in import policies, unpopular as this stipulation is at this time. Despite the difficulties in payments, the capital goods import plan has been fulfilled over the last 9 months, although considerable shortfalls have been noted in imports of consumer supply goods (with respect to both the first and the second payments area).

In farming, the situation is also very tense. Although grain yields and crops this year are better (approximately 10 percent in crops) than a year ago last year, they are much worse than planned. According to estimates, the potato crop will be the lowest in 20 years (nearly 25 percent below last year's figure). The sugar beet crop will also be poor, so that sugar production will substantially decrease in comparison with the already adverse results of last year.

The poor results in plant production are bound to affect cattle breeding and, ultimately, state procurement of meat and milk. In order to prevent further disintegration of the foodstuffs market, and to assure a minimum supply for everyone, it appears necessary in this situation to institute meat rationing, and perhaps butter rationing as well. This must be seen as a necessary evil, but no other solution is in sight.

Clearly, the situation in industrial production and in farming must affect the domestic market. In the current year the gap between incomes and the supply of goods and services will increase. While in 1978 net market deliveries per 100 zlotys of monetary income amounted to approximately 98 zlotys, the 1979 figure was 96 zlotys and in 1980 it will be 90 zlotys. This is, of course, a financial index that falls short of reflecting imbalances in product mix, quality and other factors.

The Production Contract

These fragmentary and incomplete data do portray, to a great extent, however, the dramatic situation of our economy. Deliberately omitted from the discussion presented above were the matters concerning investments and construction, requiring separate analysis based on more complete data than are available to me. In general, it can be said, however, that things are not going the right way in this area--the outlays (this is to say, money expended) will conform with, or slightly exceed, the planned figures, while substantive results will be significantly lower. Unless we halt not several, but several dozen, ongoing investment projects, we will be unable to put our investments in order, and thus reverse the trend described above. It will be impossible, as well, to institute indispensable modifications in investment structure.

This dramatic situation did not arise in the last few weeks or months. It had been developing because of increases in materials intensiveness and imports' intensiveness for production, because of declining investment effectiveness and because of a structure of production that did not conform to society's needs. Yet in the course of several weeks or even months we will be unable substantially to decrease materials intensiveness, improve investment effectiveness, or restructure the economy. On the other hand, we have to stop--in the course of several weeks, or even days--the process of disintegration and abrupt intensification of disproportions, and we must create a foundation for economic consolidation for implementing socially the most important tasks.

In pointing out the need for various ad hoc measures (which are needed in much greater numbers than suggested in this article) I frequently referred to centralization of particular decisions. At the same time, I reaffirmed the exceptionally urgent need for renewal in the methods of economic management. This can be seen to contain contradictions because, among other things, excessive centralization is now blamed for the current dramatic situation of our economy, while decentralization is perceived as a measure for removing existing errors and deficiencies.

Indeed, the centralization of the last few years was endowed with all the shortcomings of this method, while being deprived of its advantages.

This is to say, centralization incapacitated the enterprises and largely absolved them of responsibility, while failing to concentrate the forces and materials in the socially most important sectors. It neutralized the initiative and activity of immediate producers directing their efforts to the accomplishment of frequently formal, neither economically nor socially justified, indexes. Still, it did not assure effective control over investment processes and the distribution of scarce resources in a fashion justified by the needs. It failed to overcome, and frequently incited, particular interests, thereby intensifying, or allowing the intensification of, most of the imbalances.

Of course, this is not what I mean when I refer to centralization. I believe, however, that in an emergency situation--which is what our economy is in at this time--there is a need for extremely flexible management, indeed, command from one single center. It is not possible to refer to cost effectiveness calculations

performed on the ministry level or on subbranch level when a number of ministry or subbranch interests are, of necessity, brutally and ruthlessly overruled, and when it is necessary to suffer losses, by no means small, in order to avoid much greater losses. For example, it is difficult to expect the automotive industry to offer to halt the manufacture of Polonez cars, and the Unita factory can hardly be expected to refrain for a specified period from manufacturing color television sets, though these are the kind of decisions that must be made at this time. Similarly, difficult as it is for a particular subbranch to yield to another subbranch all of its allocated import resources when it is evident that such a move would cause tremendous repercussions, possibly even the closing of certain plants. Even the best economic parameters are of no use in such situations.

Do actions of this kind, however, exclude the possibility of a change in economic management style to imbue this style with genuinely social characteristics? They certainly do nothing to facilitate this, yet at this time these processes must be reconciled as much as possible. This means that while we firmly delimit the possibilities of obtaining scarce production resources in the plans, we must conclude social contracts of a certain type with plant crews. They are the ones, after all, who will ultimately determine what will become of those scarce resources and how they will be utilized. It is necessary, therefore, to abolish most of the ceiling limits. The ones to be retained--mostly in supplies and imports--must be unequivocally defined, and their implementation must be strictly adhered to, just as in the "horizontal" contracts, i.e., those concluded with the receivers of ordered goods.

It is also necessary to abolish most of the gross type indexes without waiting for a sweeping reform. At this time, we are in no position to launch powerful efficiency incentives, but let us, at least, eliminate the counterincentives. This is the only way to create a level of understanding with plant personnel. I fear that without such a level of understanding this kind of plant personnel will simply refuse to accept the plan, which would not be worthy the paper it is printed on without acceptance of this kind.

All of these measures are temporary, of course, although their significance is tremendous at this time. Whether they will be effective depends on the wisdom, decisiveness and correct assessment of the situation on the central level, as well as on the public mood, political climate and psychological attitude of most plant crews. This, in turn, is strongly affected by the course of a number of processes not connected directly with the economy. Thus, there is perhaps little that appeals for efficient performance can achieve in this situation. Much more can be accomplished by specifically coming to terms with employee groups, treated as partners rather than adversaries on every level, and by clear exposition of the existing situation, though this would often require taking the blame because it is not the plant crews' fault that the situation is what it is. Ultimately, they are the ones to undo the results of the errors--therefore, they have a right to codetermine how to accomplish this and to closely supervise those who provide guidance from various levels.

STUDY ASSESSES PROFITABILITY OF LIVESTOCK PRODUCTION

Warsaw NOWE ROLNICTWO in Polish 1-15, 16-21 Jul 80

[Article by Adam Roznoch: "Economic Production Conditions and Developmental Trends of Livestock Production on Private Farms in 1979-1980"]

[No 13, 1-15 Jul 80 pp 10-13]

Hog Production

[Text] In this article (on the basis of the results of questionnaires distributed in November 1979 at the Institute of Agricultural Economy (IER)) we are presenting the assessment and opinions of farmers concerning the current economic production situation in livestock production and and the farmers' production intentions for 1980. The research covered a total of 4,950 private peasant farms located throughout the country, including 1,390 multipurpose farms, 1,380 farms specializing in various types of livestock production, and 1,680 farms carrying on agricultural bookkeeping.

The possibilities for developing hog production, as well as for the other types of livestock production, are determined by a host of various economic-production factors, including (particularly during short periods of a few or even a dozen and some months) first of all fodder reserves and production profitability.

The current economic-production situation in the realm of hog production is far less favorable than during the comparable period last year. Particularly unfavorable is the fodder situation, directly caused by the poor harvests of basic fodder crops, especially grain. The decline in grain production throughout all agriculture is estimated at about 4.2 million tons, which is about 19.6 percent of last year's production. This great decline in grain production was the result both of smaller grain yields, owing to the adverse weather conditions and the lower amounts of fertilizer applications, and the reduction (by 2.9 percent) in the area cultivated with grain on private farms.

(g) Percentage of farms on which current own fodder resources for hog-raising are:
(h) Adequate (i) Inadequate (j) Don't know yet (k) Have no hogs

---

The research shows that on about 79 percent of the farms the harvests of grain were lower than the previous year, while on 11 percent they were higher. The cereal crop failure occurred in all regions, being particularly severe in the following regions*: Northeastern (II), Central Eastern (VI), Central (I), and Central Western (VII).

A far more favorable assessment was assigned to harvests of potatoes, up by about 6.3 percent over last year throughout agriculture as a whole. Larger potato harvests were noted on more than 57 percent of the farms questioned, and lower only on 16 percent, by contrast. The relatively better potato production this year was found in the following regions: Northeastern (II) and Northern (III), in which larger harvests occurred on about 82 percent of the farms.

Nevertheless, it should be mentioned that many of the farmers who gave a favorable assessment of potato harvests pointed out the grave difficulties in handling them properly, because the small number of steamer columns and the shortage of coal on many farms made it impossible to ensilage the potatoes, and the shortage of straw made it difficult to pit them properly. At the same time, at many wholesale points even potatoes designated for sales within the framework of contract agreements were not accepted. In this situation one must count on the fact that the lossess in the storage of the potatoes may be substantially greater than they have usually been in the past.

Although they have greatly eased the effects of the crop failures of grain, the good potato harvests cannot completely make up for the shortage of grain fodder, which is felt exceptionally keenly in the production of pigs, because in this branch of livestock production resources of grain and industrially-produced feed have a decisive influence on the general fodder situation. This is also why the assessments of the farmers asked about the general fodder situation for hog production are not very favor-

---

*The division into regions is based on the principles adopted by the Planning Commission of the Council of Ministers, as follows: Region I -- Central, Region II -- Northeastern, Region III -- Northern, Region IV -- Southern, Region V -- Southeastern, Region VI -- Central Eastern, Region VII -- Central Western, and Region VIII -- Southwestern.

able. From them we see that at present more than 38 percent of the farms state the fodder situation for hogs is worse than a year ago, and it is better on only about 17 percent of the farms (Table 1).

According to the estimates of our respondents, the fodder resources accumulated will fully meet the needs up until the next harvests on only about 37 percent of the farms, but on one farm out of every three they are inadequate. About 14 percent of the farmers could not yet say for certain just how their fodder situation would turn out (Table 2). A particularly difficult fodder situation is occurring on those farms which specialize in hog production, farms which to a great extent base their production on their own fodder. On about 67 percent of these farms, the fodder resources accumulated are inadequate to meet complete production demands.

In the regional breakdown, the greatest shortage of fodder is found in the following regions: Central (I), Northeastern (II), and Central Western (VII).

Worthy of note is the fact that only 27 percent of the farmers suffering a shortage of their own fodder intend to reduce hog production on that account. On the other hand, over 57 percent of the farmers want to maintain or even expand their production of pork slaughter animals, increasing their purchases of industrially-produced feed to that end.

The unfavorable fodder situation is making the economic conditions of hog production much worse, because the crop failure for the basic fodder crops, especially grain, is driving up their prices substantially in turnovers among farmers. The free-market price of rye (a basic fodder grain for the production of pigs), for example, increased by about 12 percent from August to December 1979 (to 643 zlotys per 0.1 ton), and reached a level more than 17 percent higher than in December 1978. Because the wholesale price for pork slaughter animals from June 1978 remain unchanged, the ratio between the wholesale price for pork slaughter animals and the free-market price for rye has become worse. In December 1979 this ratio fell to a level of 6.93, which is far below the level of the similar period in 1978 and even lower than the year 1977, when it was exceptionally unfavorable in this regard. The price ratios for the wholesaling of pork slaughter animals under contract to the free-market prices of rye and potatoes are as follows:

Year	Rye	(in December)	Potatoes
1977	7.42		15.15
1978	8.08		16.26
1979	6.93		16.10

The drop noted in the ratio of the wholesale prices for pork slaughter animals to the prices of rye, given the simultaneous decline in the ratio of livestock wholesale prices to potato prices, greatly reduced the profitability of producing pork slaughter animals.

In January 1980 there was a further drop in the ratio of wholesale prices on pork slaughter animals to the free-market prices of rye and potatoes. The price of rye in turnovers between farmers increased by more than 4 percent in relation to December 1979 prices (by nearly 21 percent in relation to January 1979 prices). At the same time there was a further rise in the free-market price of potatoes (by 4.7 percent over the December price), as the result of which the price noted in January of this year exceeded by more than 2 percent the price in the comparable period in 1979.

On the basis of observations of the past development of the market situation, we can expect the trends toward increased free-market prices on basic fodder crops for hogs to remain up until the next harvests. Therefore, if over the coming period the past hog wholesale prices remain the same, then the decline in the profitability of livestock production will pass the critical point, with the consequences normal for such a situation becoming evident.

It is true that some improvement in production profitability may be anticipated on those farms able to take advantage of the system of bonuses for fodder savings, as introduced 1 January of this year, but these will be mainly those farms which have managed to accumulate sufficient resources of their own fodder, and according to our research there are not many such farms. Therefore, it seems as though the rise in the profitability of hog production only on those farms able to adopt this system will not be able to make up for the possible effects of the decline in production profitability on the other farms. Hence, despite the obvious advantages, the system of bonuses for saving fodder cannot substitute for changes in the wholesale prices of pork slaughter animals to include all hog producers.

According to the assessments of the farmers questioned, the production of pork slaughter animals is presently profitable on about 47.7 percent of the farms, and of these it is very profitable on 9.1 percent. On the other hand, on more than 11 percent of the farms it is decidedly unprofitable (Table 3).

It is worth noting that on over 18 percent of the farms, porker production is already on the fringes of profitability (nearly unprofitable). Here we must add that even in the fall of 1978, investigations of a similar nature (conducted in this same group of farms) showed that the production of pork slaughter animals was profitable on about 54 percent of the farms, including about 14 percent on which it was very profitable. On about 8.9 percent of the farms it was decidedly unprofitable to raise porkers. On the other hand, in the spring of 1979 the percentage of farms on which livestock production was profitable declined to 48.7 percent (including 10.1 percent on which it was very profitable), and the share of farms on which it was decidedly unprofitable rose to 9.6 percent.

Relatively speaking the largest percentage of farmers (about 47-55 percent) stating that hog production is profitable falls into the group of multi-purpose farms of small size (under 7 hectares) specializing in hog production.

Despite the fact that it is based to a large extent on young pigs and concentrated feed which is purchased, the high profitability of livestock production on small farms stems first of all from the rather low level of grain consumption, which, as we have emphasized, at the present time is important in calculating the profitability of production. Agricultural bookkeeping data show that farms under 7 hectares in area use an average of about 250-260 kilograms of concentrated feed per 100 kilograms of pork slaughter animals, while farms of 15 hectares and over use about 22-26 percent more concentrated feed to produce the same amount*. In addition, small farms also use marginal fodder to feed their livestock, such as leftovers from the household, which factor reduces the production costs still further.

On specialized farms with high profitability in the production of pork slaughter animals, the relatively low grain intensiveness of production is also a factor in this profitability, because research conducted by IER** shows that these farms average 271 kilograms of concentrated feed to produce 100 kilograms of pork slaughter animals, or over 16 percent less than multi-purpose farms with 15 or more hectares, but here we must

emphasize that in the group of farms specializing in the production of pork slaughter animals, there is also a high percentage of farms which consider the production of porkers to be decidedly unprofitable. These are above all those farms which had to make additional investments to expand their hog-raising, and these investments greatly increased production costs.

Among all age groups, the greatest profitability was to be found (as in previous research) in the production of young pigs, owing to the consistent high prices for young pigs in turnovers among farmers, despite the fact that during the latter half of 1979, there was a slight drop in prices, owing to reduced demand, because GUS data show that in the period from May to November 1979 the prices on young pigs declined by about 12 percent. It is true that in December this tendency was slowed, and in January of this year there was even a rise in prices, but this increase seems temporary and to be the result mainly of the fact that socialized farms increased their purchases of young pigs during time. This is confirmed by the January livestock census, which shows a substantial shift of young pigs from the private sector to the socialized sector. As a result, on the socialized farms there was a rise in the number of young pigs, while there was a decline on the private farms.

The firm high prices on young pigs are encouraging farmers to increase their production. So too beginning in March 1979 the number of sows bred at breeding centers has still been greater than the year before (the index for the breeding of sows is remaining at a level above 100). At the same time, as the results of the January census show, the growth tendencies are remaining in the number of sows kept for raising, especially those in pig. This is creating a potential biological base for expanding the number of hogs during the next few months, but this increase will depend above all on the extent to which the economic factors of production are improved.

The current intentions of the farmers questioned show that under the present economic-production conditions, we can count on having only one farm in five increase the number of pork slaughter animals in the near future. At the same time about 16.7 percent of the farms will probably show a decline. A still smaller percentage of farmers (14.2 percent) intend to increase the number of sows, while 3.6 percent of the farmers intend to reduce the number (Table 4).

It must be stated that the farmer intentions presented concerning the further structuring of hog production are less auspicious than in the fall of 1978 or the spring of 1979. Hence, this means that if these intentions are fully carried out, then on the scale of the entire private economy during the latter half of 1980, despite the potential for improving the production situation, there may be a steepening of the current decline in the total number of hogs. This would mean a cut in hog wholesaling in 1981. Ultimately the amount of hogs at wholesale

next year will be determined by the economic conditions for the production of pork slaughter animals during the next few months and the fodder situation during the spring and summer period. Here it must be emphasized that given current resources of the farms' own fodder, hog production can be expanded on most farms, if production profitability is improved above all, because owing to the great mobility of fodder, if conditions are favorable to the profitability of production, then there can be a shift of fodder for pork production from other branches of livestock production, a shift which would help make better use of potato resources and reduce the grain intensiveness of hog production.

As we can see from the current structure of hog levels throughout all of agriculture (as shown by the January livestock census), sales of pork slaughter animals in 1980, despite some decline during the first half of the year, will probably remain at last year's level, that is, at about 1,960,000 tons, or may even slightly exceed this figure.

Alongside fodder resources and the declining profitability of production, what sort of factors are currently hampering the rise in hog production to the greatest extent? The views of the farmers questioned show that alongside the above-mentioned factors, on more than 27 percent of the farms greater hog production is also limited by the small labor supply. This fact is especially frequently mentioned on farms of small and intermediate size (under 10 hectares), on which we find the largest number of farmers (about 25-32 percent) over the age of 60. The shortage of labor on these farms is accentuated by the very great undermechanization of hog production and the difficulties in buying appropriate farm machinery and tools.

Up until recently one could still talk about certain labor reserves on private farms, but now, along with the development of nonagricultural sectors of the national economy which are creating a great demand for labor resources, these reserves have already been exhausted. On the other hand the process of substituting machine labor for human labor is taking on greater significance. This places before economic policy the task of accelerating the development of agricultural mechanization, which was emphasized with particular force in the resolution of the Eighth Party Congress.

In second place among the factors standing in the way of increases in hog production, about 18.5 percent of the farmers list an inadequate supply of concentrated feed. Here we must add that difficulties in buying concentrated feed were listed by far more, half of all the farmers questioned. These difficulties mean that despite the high grain prices on the free market, more than 80 percent of the farmers would prefer at present to allocate grain for fodder rather than sell it and count on buying concentrated feed.

The shortage of coal is also an important barrier to increased hog production. This factor is listed as that which most seriously impedes an increase in production on more than 14 percent of the farms, and more than 75 percent of the farmers mention difficulties in buying coal.

An equally important factor making it impossible to increase the number of pigs is the question of farm buildings. Here it must be emphasized that in 1979 about 8.7 percent of the farms questioned undertook the construction of new facilities for hogs, but (mainly because of a shortage of building materials) only a third of these fully completed the investments they had begun.

The shortage of livestock facilities and difficulties with building new ones are making it impossible to expand the raising of pigs on about 13.6 percent of the farms.

Summing up, then, we can say that alongside the factor of profitability, a rise in hog production will depend at the present time on the size of the deliveries of the means of production from outside agriculture above all.

[No 14, 16-31 Jul 80 pp 29-31]

Cattle Production

[Text] The current economic-production situation in the realm of cattle production is similar to that in the realm of the production of pigs,* that is, it is much worse than last year. To a great extent this is the result of an unfavorable situation regarding fodder for cattle after the most recent harvests. According to the assessments of the farmers we questioned, the recent harvests of fodder crops were higher than last year on only 40 percent of the farms. On more than 21 percent of the farms, and on a whole 40 percent of the farms in the Southwestern Region, on the other hand, there was a substantial decline in them. On nearly one out of every three farms investigated smaller harvests of meadow hay were also noted. Similar to the case of fodder crops, most of the farms (over 45 percent) on which there was a decline in the harvests of hay are located in the Southwestern region. GUS estimates show that total harvests of meadow hay throughout agriculture were about 2.5 percent lower than last year. A serious decline (of about 13 percent) was also noted in the production of sugar beets, the leaves and pulp of which represent an important element of cattle feed. There were smaller sugar beet

*The economic-production situation for the raising of hogs was presented in the first part of this article, published in No 13, 1980

harvests on one farm out of every four which was engaged in the cultivation of sugar beets, and in the Southwestern region this figure was even one out of every two investigated. There has also been a universal decline in harvests of cereal straw, which usually played an important role in supplementing cattle feed resources, and in addition it is an important bedding material for stalls. As the result of the unfavorable harvests, more than 30 percent of the farmers say that the current fodder situation for cattle is worse than it was a year ago. On the other hand, nearly 26 percent of the farmers disagree. On more than 35 percent of the farms the fodder situation remained unchanged (Table 1). The relatively least favorable situation compared to last year is judged to be the fodder situation on farms specializing in raising milk cattle, an area which features the greatest dynamics for the growth of milk production. The production scale on these farms is strictly adapted to the resources of the farms' own fodder. For this reason any sorts of changes in fodder production are felt particularly keenly on these farms.

In the regional structure the greatest number of farmers assessing the current fodder situation as worse than last year are located in the Southwestern and Central Eastern regions, where the greatest decline in harvests of basic feed crops for cattle occurred.

According to the estimates of our respondents, the fodder resources currently held on every other farm are fully adequate for the planned number of head of cattle up to the period when they will shift over to the summer feeding system. On the other hand, we know now that on about 13 percent of the farms the accumulated fodder resources are not adequate (Table 2).

The largest percentage of farmers assessing fodder resources as adequate is located in the group of farms specializing in the production of beef slaughter animals and milk. This means that despite the relatively worse fodder situation compared to last year, particularly on farms specializing in milk production, the fodder resources accumulated on most of these farms will make it possible for them to carry out their production plans in full. Here it must be pointed out, however, that it is in this group of farms that we find at the same time the largest percentage of farmers (18-20 percent) who say that the fodder resources they currently have on hand are inadequate. These are usually farms in the Central Eastern and Central regions. The unfavorable fodder situation for cattle has greatly worsened the economics of cattle production and brought about a fixed decline in the total number of head of cattle, including young beef for slaughter in particular, because during a period of fodder problems, the farmers first of all eliminate the raising of young slaughter cattle, and only during the next phase do they begin to select cows for removal. This fact is confirmed by the results of the January livestock census, which shows that the total of number of head of cattle on private farms declined by 3.4 percent, while the number of cows declined 2.2 percent. At the same time, however, it is

(b) Very profitable
(c) Profitable but not profitable enough
(d) Hardly profitable at all
(e) Decidedly unprofitable
(f) Difficult to say
(g) No response

worth mentioning that during recent months we have observed some rise in farmers' interest in raising cattle, as shown first of all by the decline in the number of calves designated for sale and for slaughter. During the final quarter of 1979 the total sales of calves and untreated hides was 13.2 percent lower than during a similar period in 1978. The larger number of calves being fattened is creating the biological potential base for a rise in cattle production in fiscal 1980-1981. This growth will depend, however, both on the economic production factors and on the future fodder situation.

According to the assessments of the farmers we questioned, cattle-raising overall, despite the worsening of economic production factors, is still considered the most profitable sort of livestock production on most farms. This opinion is shared by more than 58 percent of the farmers. Only 29 percent of our respondents said that hog-raising was the most profitable sort of livestock production.

At the present time, similar to previous questionnaire research, the production of milk is considered to be the most profitable (Table 3).

Over 30 percent of the farmers say that milk production on their farms is very profitable, while about 39 percent say that it is indeed profitable but not profitable enough. About 5 percent of the farmers, however, say that milk production is decidedly unprofitable, and on farms which specialize in milk production this figure is 12 percent. These assessments are far less favorable than those presented in the fall of 1978 and the spring of 1979.

Nonetheless, it must be mentioned here that these assessments come from the period before the rise in wholesale milk prices which was introduced this past February. This increase (of 60 groszy per liter) significantly improved the profitability of production and will bolster the growth trends in the production and wholesaling of milk noted during the past few months. During the latter half of 1979, after a previous decline of several months, milk wholesaling was higher than during the similar period the previous year by about 5 percent. The intentions farmers have had up until now lead us to believe that during the next few months on one farm out of every five questioned we can expect a rise in the number of cows, but on about 12 percent of the farms there is the possibility that it will decline (Table 4). These tendencies are the most favorable in the Southeastern region, where a whole 39 percent of the farmers plan to increase the number of cows, while 11 percent plan to reduce it.

On the other hand, about 37 percent of the farmers plan to expand sales of milk, and in the Central and Northeastern regions this figure is about 46-47 percent. This means that the expansion of production and commodity orientation of milk on the farms investigated will occur not only by extensive expansion of the number of cows but also by increased milk productivity and limited internal consumption. Taking into account the fact that these intentions were expressed by most farmers before

(g) No response

the announcement of the rise in wholesale milk prices, we can imagine that now even more farmers are planning to increase milk sales.

Farmers' intentions in the realm of the production of slaughter beef animals (Table 4) are far less favorable than those for milk production. The percentage of farmers who intend to increase the number of head of beef slaughter animals equals the percentage of farmers with the opposite intention. Taking into account the fact that the farms which we asked are usually stronger economically than the average for the country, and therefore have more progressive production attitudes, on the scale of all private agriculture we should count on the possibility that the decline in the number of head of beef slaughter animals may be maintained in the near future, and along with this will go a decline in the production and wholesaling of beef slaughter animals. In order to turn around these trends, it is essential first of all to raise the wholesale prices on beef slaughter animals as quickly as possible.

The research shows that at present the profitability of the production of beef slaughter animals is not assessed to be very great either in absolute terms or in comparison to other directions of livestock production. Nearly 4 percent of the farmers believe that slaughter beef production is decidedly unprofitable, and 9 percent believe that it is on the borderline of profitability (nearly unprofitable). The profitability of slaughter beef production is assessed to be particularly unfavorable on farms which specialize in cattle production, including both those specializing in milk and those specializing in slaughter beef (Table 5).

Compared to the production of pork slaughter animals, beef slaughter animals are considered to be more profitable on only 26 percent of the farms, while the opposite situation exists (pork slaughter animals more profitable) on more than 28 percent of the farms. On the other hand, back in the spring the number of farmers who considered it more profitable to produce beef slaughter animals than pork slaughter animals was greater than the number of farmers expressing the opposite opinion.

Compared to the production of milk, the production of beef slaughter animals is currently more profitable on about 18 percent of the farms, while on more than 54 percent of the farms it is considered to be more profitable to raise milk cows.

Alongside the fact that production is not very profitable in either absolute or relative terms, the raising of beef slaughter animals, similar to that of milk cows, is limited by a number of various other factors. Among the most important of these, one farmer out of every five questioned lists the shortage of labor and undermechanization.

[Key]
(a) Percentage of farms assessing the production of slaughter beef animals to be:
(b)-(h) and (1)-(9) as in Table 3

In second place (about 17-19 percent of the farms) is listed the shortage of the farms' own fodder, and on about 13 percent of the farms the cause of this shortage is the lack of good meadows and pastures.

On one farm out of every ten the lack of farm buildings and difficulties in constructing them is a barrier to the development of cattle production.

A similar percentage of farmers considers the difficulties in buying animals for raising and the high prices on them to be the major factor making it difficult to increase cattle production, especially milk cattle production. According to GUS data, the mean price of a one-year old heifer on the free market exceeded 9,000 zlotys in October 1979 and was about 7 percent higher than during a similar period the previous year. The price of heifers although it is listed by farmers as a factor standing in the way of production growth, shows the increased interest in expanding the number of milk cows.

Further down the list of factors having the most adverse effect on growth of cattle production we find inadequate supply of concentrated feed and coal, as well as poor wholesale organization and abuses in the wholesale points, especially in the case of milk.

Therefore, in general we can say that the possibilities for a further increase in livestock production, as for all agricultural production, after all, depends mainly on the creation of economic conditions favorable

to production and on the influx of a stream of the basic means of production from nonagricultural sectors of the national economy. Here it is mainly a question of insuring agriculture supplies of proper farm tools and machinery, coal, chemical fertilizers, building materials, and also concentrated feed mixes. The significance of this issue was emphasized particularly strongly during the deliberations of the Eighth Party Congress.

BRIEFS

SWEDEN-POLAND FERRY DISCONTINUED--Ferry services between Karlskrona and Gdansk in Poland will be discontinued on 5 January, according to Radio Blekinge. The route was established a year ago and was to be run experimentally for 3 years. The Polish side has now declared they can no longer receive tourists owing to the current political and economic situation in the country. The present shortage of food in Poland is said to be a strong contributory cause. In Poland it is considered likely that the ferry services can be reestablished after 2 years at the earliest. SUCCESSES OF AERONAUTICAL INDUSTRY DISCUSSED

Bucharest VEAC NOU in Romanian No 11, Nov 80 p 3

[Article by George Popescu: "Romanian Airplanes--Praise and Records"]

[Text] Inheriting a tradition of more than half a century, the Romanian aeronautical construction industry is currently experiencing an unprecedented development, illustrated by the realization of a full range of aviation programs, from gliders to agricultural planes, from helicopters to the ROMBAC 1-11 intermediate range courier airplane. These airplanes are being constructed on the basis of original designs or in collaboration with partners with a strong tradition in this field such as the USSR, France and England.

A number of achievements of Romanian airplane designers and builders are registered among the successes obtained by the Romanian economy in all fields, especially in industry. The gliders and monoplanes of various types designed by Eng Iosif Silimon and constructed in the Enterprise for Aeronautic Constructions in Brasov have carried the traditional insignia of our aeronautical industry--IAR [Romanian Aeronautical Industry]--in almost 20 countries of North America, Europe, Asia, South America and Australia. The best known specialized reviews (SOARING in the United States, the Australian review GLIDING, AVIASPORT in France, etc) have published words of praise for Romanian gliders, stressing their good performances and irreproachable execution: "logical, solid construction," "a very competitive airplane on a par with club gliders," "I am completely satisfied with and captivated by the glider."

Also, airplanes presented during recent years at international aircraft exhibits in Farnborough, England, Le Bourget, France and Hannover, West Germany have received a good reception from the public and from specialists, thus confirming the results registered during their utilization. Among the successes obtained by Romanian gliders and motor gliders one should mention, first of all, the world record of 829 km, round-trip, achieved by the IS-28B2 bilocular glider on 7 April 1979 in Pennsylvania by the pilots Tom Knauff and Robert Tawes IV.

The same type of glider obtained an annual average of 1,000 hours of flight in clubs in Australia during the 1978-1980 period, taking first place among similar gliders utilized in this country.

Appearing on the world market in 1977, the IS-28M2 motor glider has already obtained successes which place it among the most sought-after planes in its class.

Between 15 August and 4 October 1978, the motor glider completed a flight through 48 states of the United States, with Hal Lawrence as its main pilot; this was the first circumstatal flight by an airplane of this category.

Flying three motor gliders of the same type, Australian pilots Charles William Riley, Bert Persson and William Schoon completed a veritable air rally of 22,000 km (154 hours of light) between Brasov, Romania and Tocumwal, Australia from 8 May to 3 July 1980.

These performances demonstrate both the high level of Romanian gliders and motor gliders and the ability of Romanian designers and builders to achieve increasingly more complex airplanes, with superior qualities, which are competitive on the international level.

CSO: 2700 END
